The Karaha Geothermal area has two-phase steam characteristics, which is a flowing fluid consisting of steam and brine (water produced from geothermal sources). The steam is used to generate electrical energy, while the brine is reinjected back into the reservoir. Based on laboratory analysis, the brine contains many minerals with relatively high concentrations. The test results of brine sample from Pond KRH 4 at the Quality Testing Laboratory in the Kamojang area indicate that the brine contains minerals needed by plants, such as macro nutrients and micronutrients. To support operations in the Karaha area, routine grass cutting activities are carried out throughout the Geothermal Power Plan Area and geothermal well clusters. The grass cutting work can generates waste from wild grass cuttings amounting to 110 tons per year, which can cause various environmental issues. These issues include creating habitats for snakes that can endanger workers conducting patrol checks or causing blockages in water flow paths within the drainage system.

Currently, the utilization of geothermal energy in the PGE Karaha area is only in the form of indirect use, which is the conversion of geothermal energy into electricity. The absence of derivative products from geothermal energy becomes one fact that needs to be resolved, as it aligns with the directive from the President Director of Pertamina Persero, Vision and Mission of PT PGE company, and KPI of President Director PT PGE related to secondary revenue initiative. One effort to solve this problem is to create an innovation by utilizing cut wild grass combine with geothermal hot water (brine) to produce a marketable product in the form of solid organic fertilizer for plants. COMBINE (Compost Brine) fertilizer is answer for the solid organic fertilizer produced, which contains macro and micronutrient elements that meet the requirements of the Indonesian National Standard (SNI) for compost quality standards 19-7030-2004. The production of COMBINE fertilizer is carried out using a formula consisting of 150 ml of EM-4 solution, 150 grams of molasses, 15 liters of brine, and 80 kg of waste from wild grass cuttings, with a composting time period of 1-2 months.

The innovation of the COMBINE fertilizer has been implemented in farmer groups around the area as a corporate social responsibility (CSR) program, and this innovation can also be replicated to other geothermal areas. The positive impacts of the COMBINE fertilizer innovation for the company and the community around the geothermal working area of the Karaha are as follows: Minimizes the accumulation of organic waste from wild grass cuttings, thus eliminating habitats for venomous snakes that could endanger workers, COMBINE fertilizer has the potential to increase company revenue if commercialized, With using of COMBINE fertilizer provides positive impacts on soil compared to the use of chemical fertilizers, Provides a solution regarding the lack of fertilizer supply to local farmers around the Karaha area, and Establishes mutually beneficial cooperation between the community and company related to the development of COMBINE fertilizer.

1. INTRODUCTION

PT Pertamina Geothermal Energy Tbk (PGE) manages a part of the geothermal working areas in Indonesia. One of the geothermal working areas managed by PGE is the Karaha Chakrabuana geothermal working area. PGE Karaha Area operates a Geothermal Power Plant (PLTP) with an installed capacity of 30 MW. Currently, PGE Karaha Area manages 6 production wells, 1 injection well, 3 injection wells under study status, and 1 well under recovery status. These wells are located in several clusters: production well KRH 4-1 and injection study well KRH 4-3 are located in cluster KRH 4; production well KRH 5-1, injection study well KRH 5-3, and recovery well KRH 5-2 are located in cluster KRH 5; injection well KRH 2-1 is located in cluster KRH 2; injection study well KRH 6-1 is located in cluster KRH 6; and production wells TLG 3-1, TLG 3-2, TLG 3-3, TLG 3-4 are located in cluster TLG 3. The Karaha geothermal area covers a vast region, consisting of the Fluids Collection and Reinjection System (FCRS) and the Geothermal Power Plant (PLTP), with a geothermal working area of 55400 hectares in a mountainous region.

With such a vast geothermal working area, it is necessary to pay attention to and treat environmental aspects. For example, grass that grows in the work area must be regularly cut to prevent it from becoming a habitat for venomous animals such as snakes which could endanger workers as shown in Figure 1. To support operations in the Karaha area, routine grass cutting activities are carried out throughout the geothermal power plan area and geothermal well clusters. The grass cutting work can generates waste from wild grass cuttings amounting to 110 tons per year which can cause various environmental issues. The accumulation of organic waste presents both a problem and an opportunity if managed properly. The opportunity that can be taken with organic waste in the form of wild grass cuttings is to use it as a raw material for compost fertilizer.

Figure 1: The condition of wild grass in the separator area of Cluster KRH 4.

Figure 2: The condition of Pond Cluster KRH 4.

The Karaha Geothermal Area has two-phase steam characteristics, which is a flowing fluid consisting of steam and brine (water produced from geothermal sources). Steam and brine are first separated in the separator, with the steam directed to the geothermal power plant (PLTP) to generate electrical energy, while the brine is reinjected back into the reservoir. There are two types of reinjection systems in Karaha area it is the hot reinjection system and the cold reinjection system. In the hot reinjection system, the brine from the separator is directly channeled to the reinjection well located in the same cluster, such as in clusters Karaha 5 and Karaha 6. In contrast, the cold reinjection system involves directing the brine from the separator to a pond as shown in Figure 2 for cooling before it is reinjected into the reinjection well, as seen in cluster Karaha 4.

Based on laboratory analysis in Figure 3, the brine contains many minerals with relatively high concentrations. The test results of brine sample from Pond KRH 4 at the Quality Testing Laboratory in the Kamojang area indicate that the brine contains minerals needed by plants, such as macro nutrients (potassium 1154.76 ppm, calcium 773.8 ppm, magnesium 0.45 ppm), and micronutrients (sodium 4547.96 ppm, silica 366.49 ppm, chloride 9540.22 ppm, boron 185.10 ppm, lithium 19.08 ppm). The brine water can be utilized as an additional raw material in the production of compost fertilizer, thereby enhancing the macro and micronutrient content.

Currently, the utilization of geothermal energy in the PGE Karaha area is only in the form of indirect use, which is the conversion of geothermal energy into electricity. The absence of derivative products from geothermal energy becomes one fact that needs to be resolved, as it aligns with the directive from the President Director of Pertamina Persero, Vision and Mission of PT PGE company, and KPI of President Director PT PGE related to secondary

revenue initiative. One effort to solve this problem is to create an innovation by utilizing cut wild grass combine with geothermal hot water (brine) to produce a marketable product in the form of solid organic fertilizer for plants.

2. LITERATURE

2.1 Compost

Compost can be defined as the result of the decomposition of organic matter, while composting is the process which organic matter undergoes biological decomposition, particularly by microbes that utilize organic matter as an energy source (Adewumi et al., 2005; Hansen et al., 2006). The composting process is a natural one, where organic matter biologically decomposes through microorganisms that convert organic material into an energy source. During compost process production, a balanced mixture of materials is combined, sufficient water is added, ensuring good aeration, and adding activators to accelerate the composting process (Isroi, 2008).

2.1.1 Composting Time

The duration of composting depends on the characteristics of the materials being composted, the composting method used, and whether composting activators are added. Naturally, composting can take from several weeks to two years for the compost to be fully mature (Rynk et al., 1992). Mature compost feels soft when crushed because during the composting process, organic matter undergoes decay and decomposition, resulting in changes from fresh material to amorphous, dark-colored microbial substances. This substance is akin to soil material (Sutedjo et al., 1991). Compost maturity is influenced by various factors during the composting process. After composting is complete, the raw materials will change color to a dark brown (Indriani, 1999).

2.1.2 Quality of Compost

The quality of compost is greatly determined by its maturity level, in addition to its heavy metal content. Organic material that isn't fully decomposed can have detrimental effects on plant growth. Generally, mature compost exhibits the following characteristics: Dark brown to black color and crumbly texture; Insolubility in water, although some parts of the compost can form a suspension; Highly soluble in alkaline solvents, sodium pyrophosphate, or ammonium oxalate solution with producing a dark extract that can be further fractionated into humic, fulvic, and humic substances; a carbon to nitrogen ratio ranging from 20 to 40, depending on the raw materials and degree of humification; high cation exchange capacity and water absorption capability; beneficial effects on soil and plant growth when applied to soil; a temperature almost the same as the ambient air temperature; absence of volatile fatty acids and odorless (Sutanto, 2002).

The carbon to nitrogen (C/N) ratio is an important parameter, which will relate the composting reactions to the relative concentrations of essential chemical constituents required for the growth and metabolic reactions of the microbial population. Compounds such as carbohydrates, in addition to being sources of carbon for the microbial biomass, will generate energy required for the microbial metabolic activity. Nitrogen is an essential component of proteins and amino acids required for the growth of the microbial biomass. Generally, it is recommended that, to maintain an active microbial population in a composting operation, the available carbon to nitrogen ratio should be kept at appropriate levels. Lower ratios will result in losses of nitrogenous compounds, while higher ratios will retard the composting reactions (Inbar *et al.,* 1991).

2.1.3 Functions of Compost

Compost has properties that improve soil structure, increase the binding capacity of sandy soil, enhance soil binding capacity, promotes better drainage and air circulation in the soil, aid in the decomposition of mineral materials, provide nutrients for microbes, and reduce the activity of harmful microorganisms (Yovita, 2001). According to Isroi and Yuliarti (2009), the way to restore soil fertility is by using organic fertilizers such as compost, which is believed to enhance soil fertility. Organic fertilizers can mitigate the adverse effects of chemical fertilizers and also restore soil fertility to its original state. Mayadewi (2007) also supports this view, who asserts that organic fertilizers are among the types of fertilizers that contain nutrients supporting soil fertility and the growth of soil organisms. Organic fertilizers have natural properties that do not harm the soil and provide macro elements such as nitrogen, phosphorus, and potassium, as well as micro elements such as iron, zinc, boron, cobalt, and molybdenum.

2.1.4 Benefits of Organic Fertilizer

According to Primantoro (2001) and Sutanto (2002), the benefits of using organic fertilizer are as follows:

1. Organic fertilizer functions as a granulator, thereby can improving soil structure. The presence of organic matter can bind soil particles in larger aggregates, making the soil looser. In sandy-textured soil, organic matter will increase the binding between particles.
2. The soil's water absorption capacity can be increased with the application of organic fertilizer, as it can biding more water and for a longer period.
3. Organic fertilizer can improve the living conditions within the soil. Soil microorganisms play a crucial role in organic matter transformation. With the presence of organic fertilizer, microorganisms actively decompose the organic matter because it provides them with energy, allowing nutrients in the soil to be absorbed by plants. Soil rich in organic matter will accelerate the proliferation of fungi, bacteria, microflora, and microfauna.
4. The nutrients in organic fertilizer are a food source for plants. Although present in smaller quantities, organic fertilizer contains a complete range of nutrients and serves as a source of essential elements such as nitrogen (N), phosphorus (P), and sulfur (S).

2.2 Macro and Micronutrients

The nutrient content in compost is quite comprehensive, encompassing both macro nutrients (N, P, K, Ca, Mg, S) and micronutrients (Fe, Cu, Mn, Zn, Mo, B, Cl) that are essential for plants growth. Although the nutrient content in compost is not as high as in chemical fertilizers, it still plays a crucial role. Consequently, compost is usually applied in larger quantities compared to chemical fertilizers (Isroi and Yuliarti, 2009).

Another advantage of compost lies in its organic matter content, including humic and fulvic acids, which are beneficial for stimulating plant growth. In the short term, compost usage can improve the physical properties of soil and increase soil biological activity by supplying some of the plants' nutrient needs. In the long term, compost application can restore soil fertility and productivity (Isroi and Yuliarti, 2009).

To determine the quality of compost, it is necessary observations of its physical properties such as color, odor, and texture. Generally, successful composting is categorized as complete or effective when the physical quality

of compost meets the quality criteria specified in the Indonesian National Standard (SNI). The Indonesian National Standard (SNI) refers to international compost quality standards such as the British Colombia Class I Compost Regulation dan Standard of Canada (CAN/BHQ 0413-200), especially regarding heavy metal micro-nutrient quality with permissible maximum values and also refers to compost products produced by various compost producers in Indonesia. Indicators used to assess organic fertilizers include pH and organic carbon content. The pH according to the Indonesian National Standard (SNI) 19-7030-2004 ranges from 6.80 to 7.46, potassium (K_2O) in organic fertilizers has a minimum value of 0.20%, and phosphorus (P_2O_5) has a minimum value of 0.01% (SNI, 2004).

2.3 Geothermal Brine

Geothermal brine or water of geothermal is the hot water product resulting from the geothermal separation process at a separator equipment. Typically, brine is directly reinjected into the reservoir as part of reservoir management efforts to prepare it for re-accommodating geothermal heat. This practice helps mitigate potential risks associated with utilizing the brine. The contents of brine include carbon dioxide (CO_2), hydrogen sulfide (H_2S), ammonia (NH_3), methane (CH_4), sodium chloride (NaCl), bBoron (B), arsenic (As), and mercury (Hg), which also pose a high potential for environmental damage.

3. DISCUSSION

3.1 COMBINE (Compost Brine) Production Process

The raw materials used in the process of making compost brine consist of the main raw materials, which are wild grass clippings and geothermal water. Additional materials such as EM-4 solution and molasses, which are used in the decomposition process of the main raw materials. The EM-4 solution is a type of liquid that contains various bacteria, including decomposers, Lactobacillus sp., lactic acid bacteria, photosynthetic bacteria, Streptomyces, cellulose-decomposing fungi, and phosphate-solubilizing bacteria, which function as natural decomposers of organic matter (Akmal, 2004). The wild grass cuttings collected from cluster areas and the geothermal power plan (PLTP) are first chopped to obtain uniform uniform-sized raw materials, into accelerate the decomposition process of the organic materials. During the composting process, the additional materials undergo decay and decomposition, resulting in changes to the fresh materials, the formation of microbial cell substances, and transformation into a dark amorphous form. This substance is referred to as “soil-like matter” (Sutedjo et al., 1991).

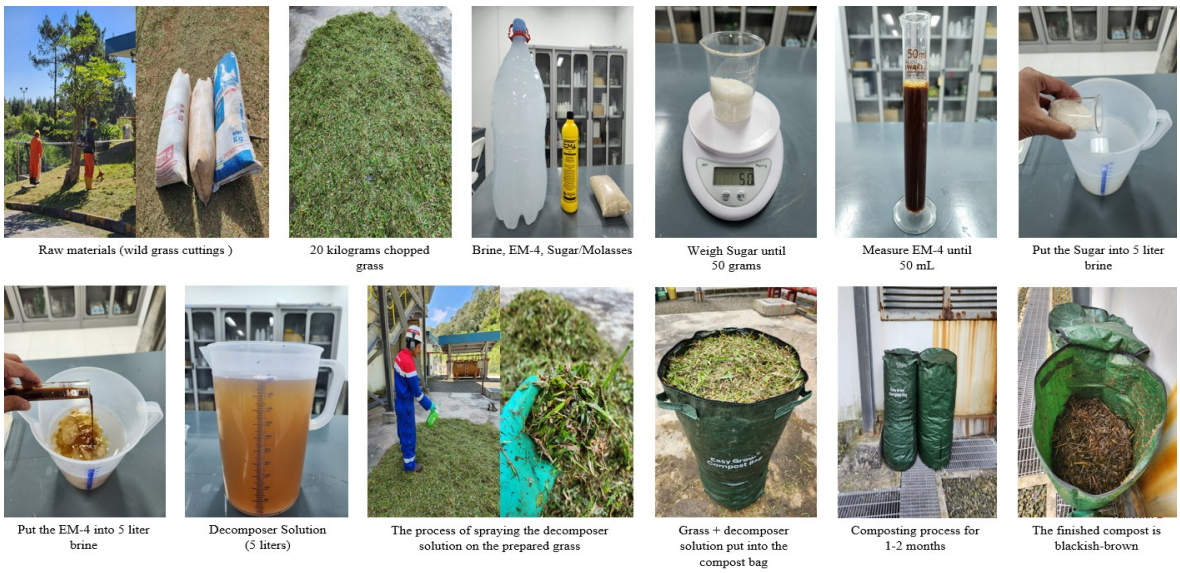

Figure 4: Diagram process of making compost brine fertilizer.

The production process of COMBINE fertilizer starts by cutting the grass into small, uniform pieces. Next, a decomposer solution is made by mixing 150 ml of effective microorganism solution (EM-4), 150 grams of molasses/sugar, and 15 liters of geothermal water (brine). This decomposer solution is evenly sprayed into 60 kg of shredded grass and placed into a compost bag for composting, which takes 1-2 months as shown in Figure 4. According to SNI 19-7030-2004 standards, compost maturity is indicated by a volume reduction of approximately 30%-40%, a dark color of compost, an earthy smell, and a C/N ratio of 10-20. Sutedjo *et. al* (1991), mature compost will feel soft when crushed because the organic materials undergo decomposition and transformation on fresh materials during composting, the formation of microbial cell substances, and transformation into a dark amorphous form. This substance is referred to as soil-like matter. After the composting process is complete, the

raw materials change color to a dark brown. The color change is caused by the activity of microorganisms working during the decomposition process. The color produced in this study has met the standard (SNI 19-7030-2004), which specifies that compost should be dark brown.

3.2 Quality Test of COMBINE (Compost Brine) Fertilizer

The produced COMBINE fertilizer has been subjected to sample testing at the Ministry of Industry's laboratory to observe the content of macro nutrients and micronutrients. Based on the analysis results in Figure 5, COMBINE fertilizer contains macro nutrients such as nitrogen 2.36%, phosphorus 10.87%, and potassium 23.32%, calcium 311.8 ppm, magnesium 3181 ppm, and contains micronutrients including sodium 6837 ppm, iron 4176 ppm, chloride 10515 ppm, copper 1.28 ppm, zinc 155 ppm, manganese 134.2 ppm, silica 366.49 ppm, boron 185.1 ppm, cobalt 1.02 ppm, and lithium 19.08 ppm.

Figure 5: Result The Quality Testing Nutrients COMBINE.

The COMBINE fertilizer is answer for the solid organic fertilizer produced, which contains macro and micronutrient elements that meet the requirements of the Indonesian National Standard (SNI) for Compost Quality Standards 19-7030-2004.

3.2.1 Nitrogen Nutrient (N)

Based on laboratory analysis results, the COMBINE fertilizer sample contains 2.36% nitrogen, which is higher compared to the Indonesian National Standard (SNI, 2004) in minimum requirement of 0.40% nitrogen content for compost. Yuwono (2005), states that organic materials with excessively high carbon content cause a prolonged decomposition process. Conversely, if the carbon content is too low, there will be an excess of nitrogen, resulting in the formation of ammonia (NH_3). Excessive ammonia content can poison bacteria and cause the necessary nitrogen to be lost. Additionally, according to Outerbridge (1991), the population of microorganisms increases or decreases according to environmental conditions in relation to the substrate.

3.2.2 Phosphorus Nutrient (P)

Based on laboratory analysis results, the COMBINE fertilizer sample contains 10.87% phosphorus, which is higher compared to the Indonesian National Standard (SNI, 2004) in minimum requirement of 0.1% phosphorus content for compost. According to Miftahul (2003), suggests that the high or low phosphorus content in compost may be due to the amount of phosphorus contained in the raw materials used and the number of microbes involved in the composting process.

3.2.3 Potassium Nutrient (K)

Based on laboratory analysis results, the COMBINE fertilizer sample contains 23.32% potassium, which is higher compared to the Indonesian National Standard (SNI, 2004) in minimum requirement of 0.2% potassium content for compost. The high potassium content in the COMBINE fertilizer is indicated to be due to the raw material from geothermal brine, which already contains a significant amount of potassium (1154.76 ppm). Sutedjo et al. (1991) state that potassium used by microorganisms in the substrate material acts as a catalyst, and their presence activity of microorganisms greatly influence the increase in potassium content. Potassium bound and stored within cells by bacteria and fungi can become available again upon decomposition. This statement is supported by Hardiani et al. (2011), who assert that potassium is used by microorganisms in the substrate material as a catalyst, and the presence of bacteria and other microorganisms significantly affects the increase in potassium content.

3.3 Implementation of COMBINE (Compost Brine) fertilizer

After the laboratory analysis of COMBINE fertilizer, it was tested on chili with three sample variations: sample 1 (chili without fertilizer), sample 2 (chili with chemical fertilizer), and sample 3 (chili with COMBINE fertilizer). Five chile were planted in each sample, measuring 30 cm by 30 cm in polybags. Ten weeks were dedicated to the collecting of data, with weekly measurements. The height of the chili, the quantity of leaves, and the quantity of fruits were among the information gathered. Chili peppers were used as samples in the trial because they have a growth period from planting to harvest of approximately 80-90 days, and the process of measuring height and counting the number of leaves is relatively easier.

3.3.1 Comparison Height of Chili

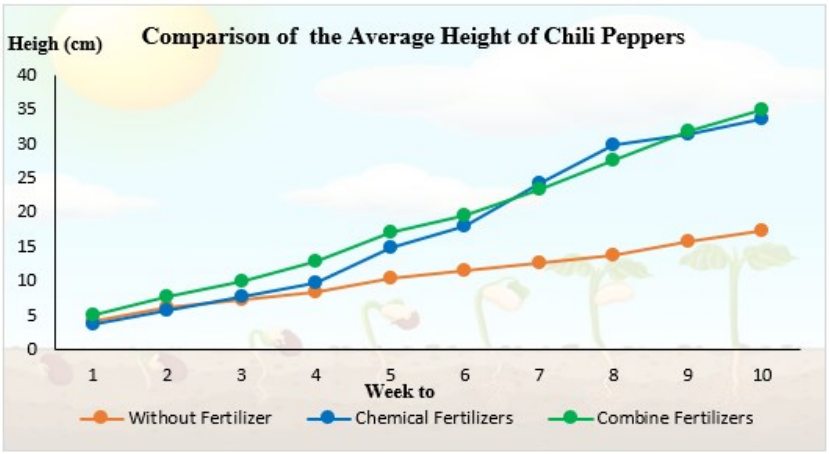

Figure 6: Comparison Height of Chili.

Based on the growth comparison height of chili in Figure 6, those without any fertilizer showed very slow and stunted growth, indicating a lack of essential macro and micronutrients which disrupted their growth process. According to Dwidjoseputro (1983), if all nutrients are available in sufficient amounts and in an absorbable form, the chili will thrive. Chili that are deficient in nitrogen grow stunted, their leaves turn yellowish-green, and if the deficiency is severe, older leaves turn yellow from the tips to the veins, then brown and dry, ultimately leading to a significant yield reduction. Conversely, if the chili have excess nitrogen, they will develop larger stems, delayed maturity, and reduced fruit quality (Hardjowigeno, 1995).

In the sample where chili was given NPK 16 16 16 chemical fertilizer in Figure 6, the growth of the chili appeared normal because all essential macro nutrients were adequately provided in high amounts. The addition of nitrogen (N) through fertilization stimulates root growth and increases root weight. Roots growing in soil with sufficient N are larger and relatively short, while roots in soil lacking N are longer, smaller, and more abundant (Marscher, 1986). The N absorbed by chili is crucial for the formation of stems, leaves, and branches. The differences in the number of branches observed reflect the varying N nutrient supply from each type of compost. The taller the chili, the more branches it forms (Nurmayulis et al., 2014).

Based on Figure 6, in the sample variation where chili was given COMBINE fertilizer, they exhibited faster, and taller growth compared to those treated with chemical fertilizer. This suggests that the macro nutrients required by the chili were well met, and the micronutrients in the COMBINE fertilizer also played a key role in their growth. Sutejo (1991) stated that adding organic matter to the soil can increase microorganism activity, such as bacteria and fungi, which function as granulators to improve soil structure. Organic matter is also used as an energy source for microorganisms, allowing them to develop and become more active (Suripin, 2002). Organic fertilizers like compost contain both macro and micronutrients, providing nutrition to chili and influencing the

number of branches per chili (Khandaker et al., 2017). Taller chili can easily access sunlight for photosynthesis. The products of photosynthesis are distributed throughout the chili to stimulate both vegetative and generative growth.

3.3.2 Comparison Number of Chili Leaves

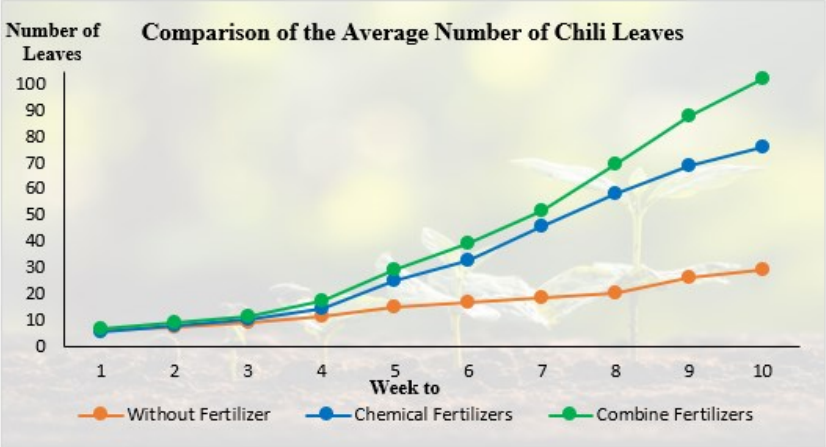

Figure 7: Comparison Number of Chili Leaves.

Based on the growth comparison number of chili leaves in Figure 7, chili that were not given any fertilizer had very few leaves, and the leaves were curled. This indicates that these chili lacked essential macro nutrients needed for leaf growth. According to Dobermann and Fairhurst (2000), nitrogen (N) can stimulate the overall growth of chili, including the leaves. The nitrogen content in chili leaves is closely related to the rate for photosynthesis, affecting the formation of biomass that serves as a food reserve for the chili, and the excess of these food reserves is stored in the fruit. Leaves that lack calcium nutrients will become curled, which aligns with Fageria et al. (1991), who stated that newly formed young leaves appear white, the growing points die (apical dieback), and the leaves curl.

In the sample variation where chili received NPK 16 16 16 chemical fertilizer in Figure 7, the chili showed many numbers of leaves due to the adequate supply of macro nutrients N, P, and K. The increased number of leaves allows the chili to maximize photosynthesis, thereby supporting their growth. Nitrogen is crucial for chlorophyll formation, which is important for photosynthesis (Pranata, 2004). However, by the 7th week, some chili leaves started to curl, which is a sign of calcium nutrient deficiency. This observation is in line with Fageria et al. (1991), who found that newly formed young leaves become white, the growing points die (apical dieback), and the leaves curl. Therefore, dolomite lime was applied in the 9th week, and leaf growth began to improve gradually. Leaf appearance can also be a significant indicator of nitrogen sufficiency in chili tissues, as nitrogen is essential for chlorophyll production, which imparts the green color to leaves (Mangel and Kirby, 1987).

Based on Figure 7, in the chili samples treated with COMBINE fertilizer, there was a higher number of leaves compared to those treated with chemical fertilizer, and there was no curling of leaves observed during the growth process. This indicates that both macro and micronutrients essential for leaf development were effectively supplied. Organic fertilizers, such as compost, provide both macro and micronutrients necessary for chili nutrition, which impacts the number of branches per chili (Khandaker et al. 2017). A greater number of leaves also facilitates more effective photosynthesis, supporting the growth of the chili. According to Surtinah (2007), good vegetative growth can also have a positive impact on the generative growth of chili.

3.3.3 Comparison Number of Chili Fruits

Based on the growth comparison number of chili fruits in Figure 8, the chili that received no fertilizer at all produced very few fruits, and fruiting only began in the 10th week. This indicates that these chilies suffered from a deficiency of macro nutrients essential for fruit development. Haryatini and Santoso (2000) state that having adequate nutrients during growth causes more active chili metabolism, which improves cell differentiation processes and ultimately leads to increased fruit weight and length. In addition to nitrogen for supporting vegetative growth, phosphorus and potassium in the growing medium also contribute to fruit development and enhance fruit quality, including fruit diameter (Gardner et al. 1991).

In the variation of chili samples treated with NPK 16-16-16 chemical fertilizer in Figure 8, the first fruits appeared in week 7, but the number of fruits was relatively low. On week 12, a fruit booster fertilizer, KNO3 and MKP, which are high in phosphorus (P) and potassium (K), was applied to accelerate the generative phase of the chilis growth. Following the application of the fruit booster fertilizer, there was a significant increase in the number of

chili fruits compared to before the booster was applied. This is supported by Nurlenawati and Nimih (2010), who state that phosphorus is essential for the generative phase of chili, especially for flower, fruit, and seed formation. High phosphorus absorption aids in cell core formation and plays a crucial role in meristematic tissue development. High levels of phosphorus in the soil solution due to phosphorus fertilization enable better nutrient absorption by chili. Lakitan (1993) also notes that potassium acts as an activator for various essential enzymes involved in photosynthesis and respiration, as well as enzymes responsible for protein and starch synthesis.

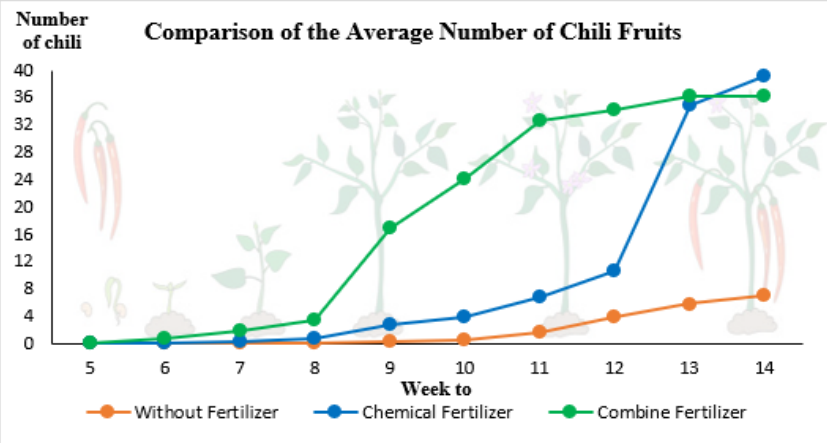

Figure 8: Comparison Number of Chili Fruits.

Based on Figure 8, in the chili variation treated with COMBINE fertilizer, the first fruits appeared in week 6, which is one week earlier compared to the chili that received chemical fertilizer. This difference can be attributed to the higher nutrient content of phosphorus (P) at 10.87% and potassium (K) at 23.32% in COMBINE fertilizer compared to the chemical fertilizer. Additionally, the increase in the number of fruits on the COMBINE fertilizer treated chili was relatively more consistent each week, indicating that both macro and micronutrients required by chili during the generative phase were effectively met. The application of organic fertilizers like compost can enhance phosphorus availability, with phosphorus playing a crucial role in flower formation and fruit maturation (Hapsoh et al. 2019). According to Harjadi (1979), fruit formation and filling are significantly influenced by nutrients such as N, P, and K, which are involved in photosynthesis processes for the synthesis of carbohydrates, fats, proteins, minerals, and vitamins, which are then translocated to the fruit storage areas. Nurhayati (2006) states that chili can be produced well if the nutrients required are available in sufficient quantities.

4. CONCLUSION

The comparison graphs of chili growth height, number of leaves, and number of fruits show that chili plants fertilized with COMBINE fertilizer have a faster growth rate, more leaves, and earlier fruit development compared to those with no fertilizer or chemical fertilizer, and they are also more resistant to pests. This demonstrates that the macro and micronutrients in COMBINE fertilizer can optimally support the nutritional requirements of chili plants throughout both the vegetative and generative stages. During the trial, COMBINE fertilizer was used only once in a 1:1 ratio of soil to COMBINE fertilizer at the planting media preparation stage.

The innovation of COMBINE fertilizer has been implemented in farmer groups around the area as a corporate social responsibility (CSR) program, and this innovation can also be replicated to other Geothermal Areas. The positive impacts of the COMBINE fertilizer innovation for the company and the community around the geothermal working area of the Karaha area are as follows:

- Minimizes the accumulation of organic waste from wild grass cuttings, thus eliminating habitats for venomous snakes that could endanger workers.
- The COMBINE fertilizer has the potential to increase company revenue if commercialized.
- With using of COMBINE fertilizer provides positive impacts on soil compared to the use of chemical fertilizers.
- Provides a solution regarding the lack of fertilizer supply to local farmers around the Karaha area.
- Establishes mutually beneficial cooperation between the community and company related to the development of COMBINE fertilizer.

Upstream Digitalization and Software in Research Department of Pertamina Part I : PertaGAMANT

Taufiq[1], Irnaka, T.M.[2], Suryanto, W.[2], Koestono, H.[1], and Mujihardi, B.[1]

[1]Technology Development I, PT. Pertamina (Persero)
[2]University of Gadjah Mada

taufiqgeophysics76@gmail.com

Keywords: upstream digitalization, non-seismic processing, noise tomography method, ground-aeromagnetic method

ABSTRACT

In the geoscience study, we require software as a data processing tool which is an important part of the Company's operational activities. In meeting these needs, Pertamina with the Research and Technology Department developed several innovations in the field of digitalization and software to assist in the processing of geoscience data, one of which is PertaGAMANT. PertaGAMANT is geophysical data processing software used to process Ambient Noise Tomography (ANT), Spatial Auto Correlation (SPAC), Gradient Density from Time-Lapse Microgravity Data, Ground Magnetic, and Aeromagnetic data. This software can be run real-time with cloud-based system, so operator or user can operate the software wherever and whenever they are with licensing system (Single Sign On) to protect confidentiality of the data.

1. INTRODUCTION

PertaGAMANT or we called Pertamina Gadjah Mada New Technology is a software to process non-seismic geophysical data processing with several module such as Ambient Noise Tomography (ANT), Spatial Auto Correlation (SPAC), Gradient Density from Time-Lapse Microgravity Data, Ground Magnetic, and Aeromagnetic data.

This software has been developed by the Research & Technology Department of Pertamina from 2020 until 2024 and has entered version 3. With this software, workers can process geophysical data to help in exploration, monitoring and field development activities.

2. METHOD

2.1 Noise Tomography Method

On noise tomography method, we have three techniques to record ambient noise data, which is pairing technique, clustering technique, and ring creation. Especially in pairing techniques, seismogram is arranged based on grid with spatial distance r so that in the cross-correlation process, one station will be correlated to all installed seismometer or station to obtain a group velocity. An illustration of the station configuration scheme (Ambient Noise Tomography method) can be seen in Figure 1.

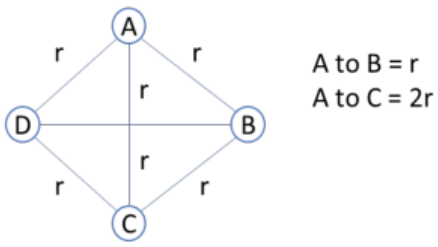

Figure 1: illustration of pairing technique on station configuration to get ambient noise data.

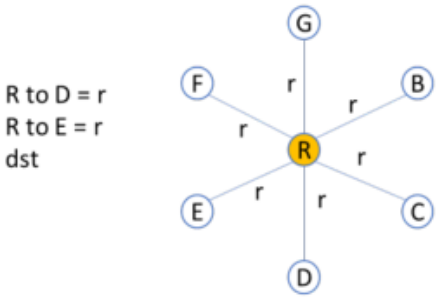

Figure 2: illustration of ring creation technique with reference station to get ambient noise data.

Clustering technique is the same as pairing techniques, but the cross-correlation process separates into several clusters, which then results from the cross-correlation will be combined in one map.

On Ring Creation Technique (Spatial Autocorrelation method), seismogram is arranged based on double triangular (north and south) like a hexagonal grid with spatial distance r. the spatial distance represents the depth penetration of subsurface velocity. An illustration of the station configuration scheme can be seen in Figure 2.

2.2 Time-Lapse Microgravity Method

Time-lapse microgravity method is the development of gravity method (x,y,z) by adding the 4th dimension of time (t). The principle of this method is to repeat gravity measurement either daily, weekly, monthly, or yearly by using a gravimeter which has an accuracy in the order of micro-Gal (Taufiq, 2015).

2.3 Geomagnetic Method

Geomagnetic Method is one of geophysical methods that used a potential field (this case a magnetic field) parameter that produced by the earth to determine a magnetic variation of rock on subsurface. Magnetic acquisition on Land is a geophysical method that measures the Earth's magnetic field anomaly on surface to determine the susceptibility variation of rocks on subsurface (derived on inversion process). In this technique can be measure with spatial distance per point on 300 meters until 1 kilometer (called detailed acquisition technique) (Taufiq, 2023).

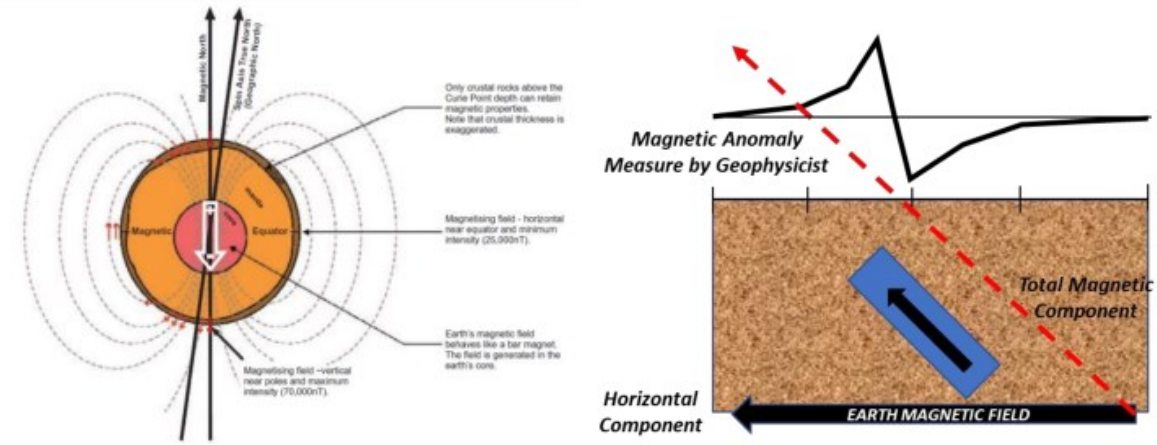

Figure 3: Illustration of Earth Magnetic Field (left) and Magnetic Anomaly measure by Geophysicist on Surface to identify subsurface condition (modified from Blakely, 1995 and Isles, 2014).

3. DISCUSSION

PertaGAMANT software can process geoscience data as in the method described above in real time because this software is operated on a cloud-based system so that users can operate the software wherever and whenever they are. Users can log in by entering the username and password (see Figure 4) that they created previously. This software is also equipped with a licensing feature which makes users feel safe when operating the software on a single-account system.

3.1 Module of Noise Tomography (ANT and SPAC) Processing

After acquisition, the data will be checked to know the quality of waveform based on threshold, event detection, and noise. Then, the data will be processed with splitting and windowing techniques to get a good condition of data. Data (after waveform preparation) is then processed with several steps as in the flowchart below (Figure 5). The differences of pairing and clustering technique are about station pairing configuration, first, the clustering technique used station pairing around measurement station with control of spatial distance. Second, the pairing technique used all the stations in the area to pair with measurement station. Last, on ring creation technique, we used reference station or central station to measure with minimum 6 station pair on grid spatial distance to process cross-correlation.

Based on the flowchart (Figure 5), with PertaGAMANT software, we can process the ambient noise data with pairing technique (see on Figure 6) and with ring creation technique (see on Figure 7). Then proses cross-correlation (Figure 8), Dispersion Curve (Figure 9), and Inversion with MCMC method (Figure 10).

3.2 Modul Gradient Density from Microgravity Processing

In this module (see Figure 11), we can create gradient (vector) density from time-lapse microgravity data to know the distribution of fluid flow direction on reservoir. This module in 2024, is still under development to adding new feature to process gravity monitoring data by time (monthly or yearly).

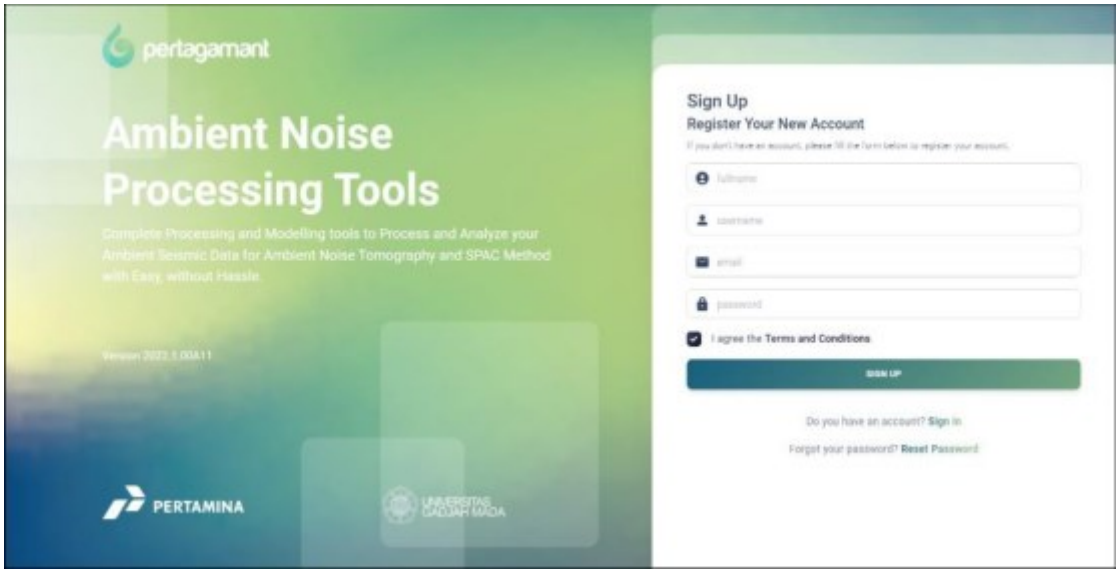

Figure 4: User Interface of software PertaGAMANT log-in system.

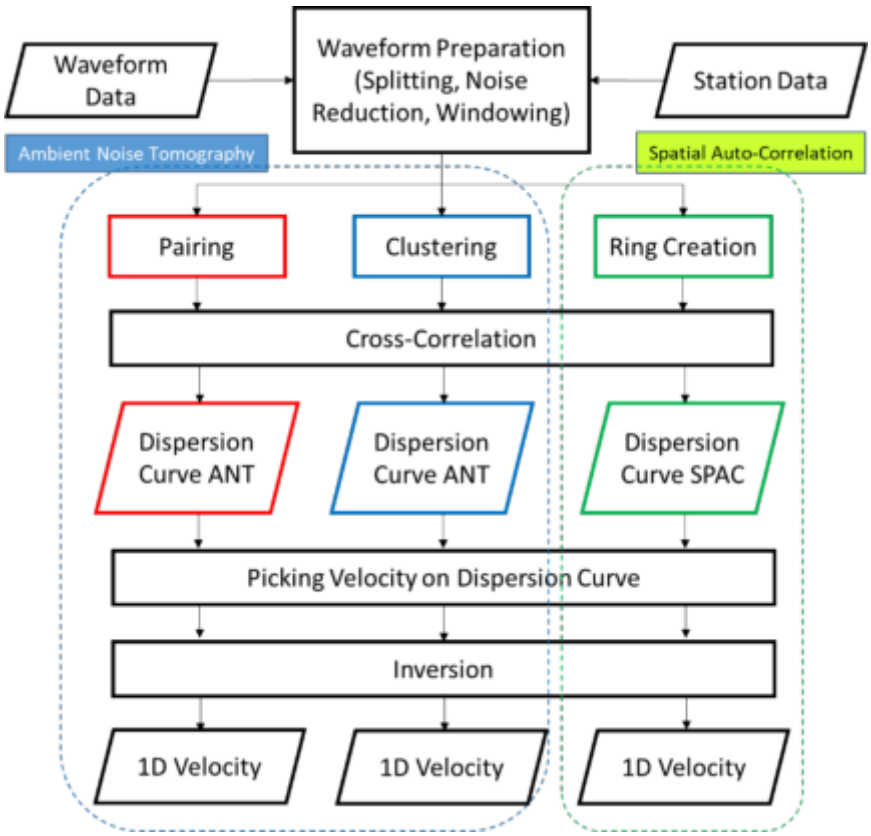

Figure 5: Flow chart to process Ambient Noise data with pairing (left), clustering (mid), and ring creation technique (right).

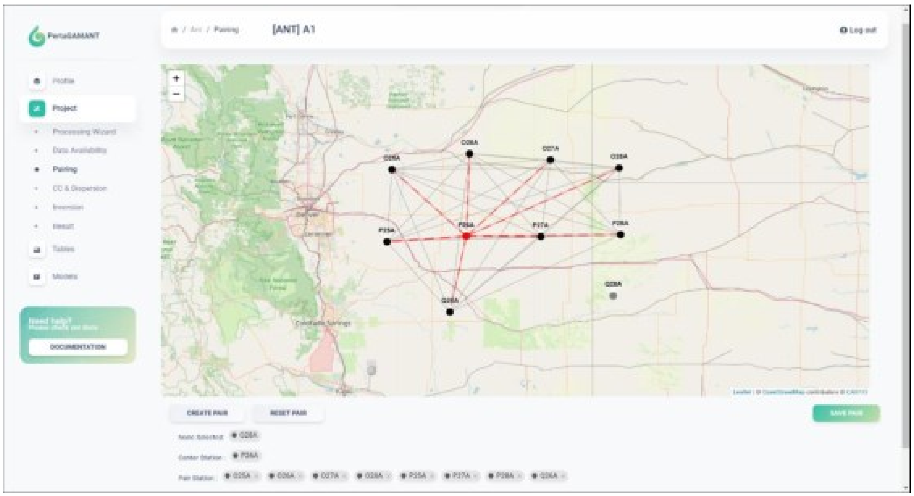

Figure 6: User Interface of software PertaGAMANT to process Noise Tomography with Pairing Technique.

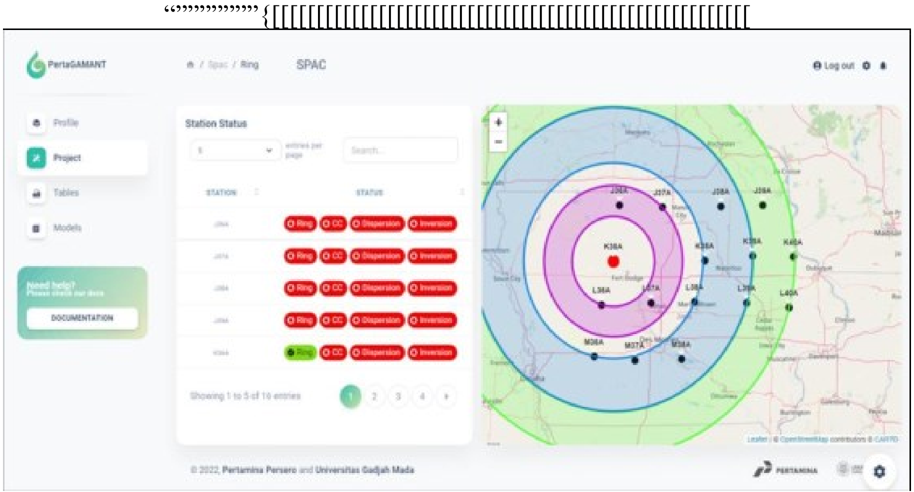

Figure 7: User Interface of software PertaGAMANT to process Noise Tomography with Ring Creation Technique.

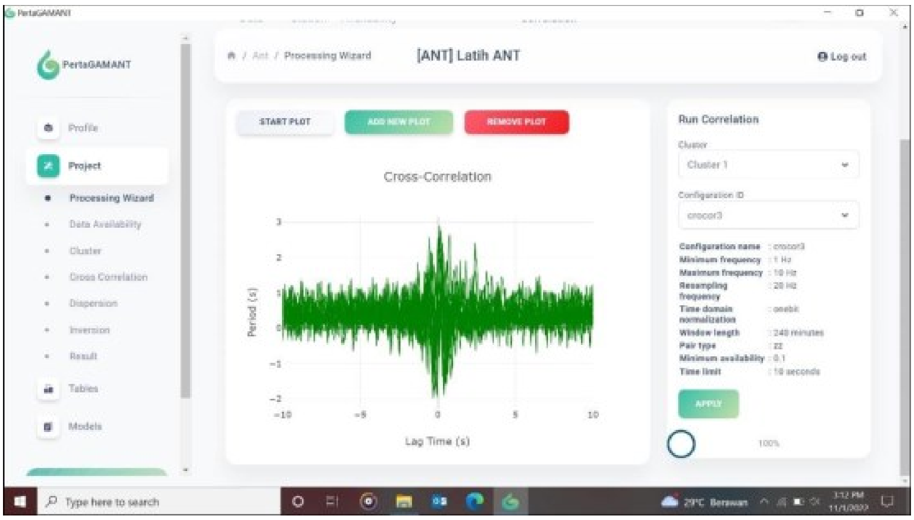

Figure 8: User Interface of software PertaGAMANT on process Cross-Correlation.

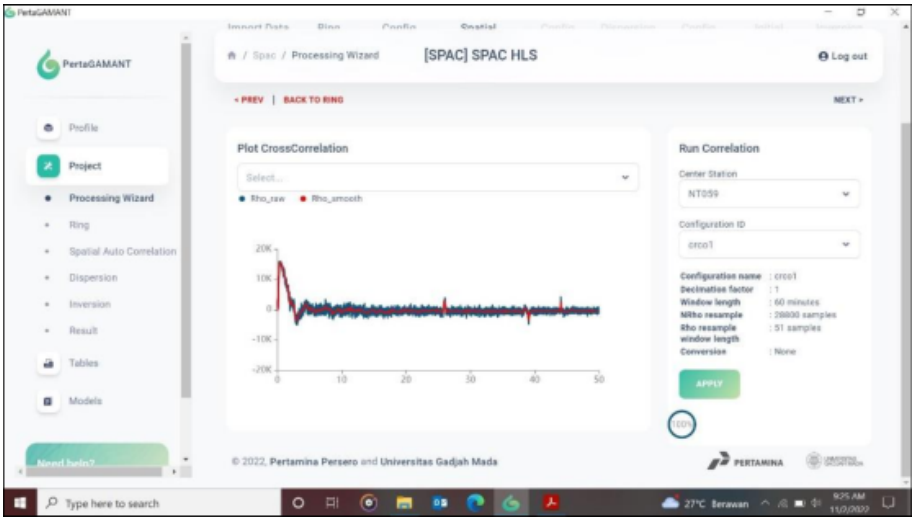

Figure 9: User Interface of software PertaGAMANT on process Picking Dispersion Curve (on SPAC).

Figure 10: User Interface of software PertaGAMANT on process Inversion.

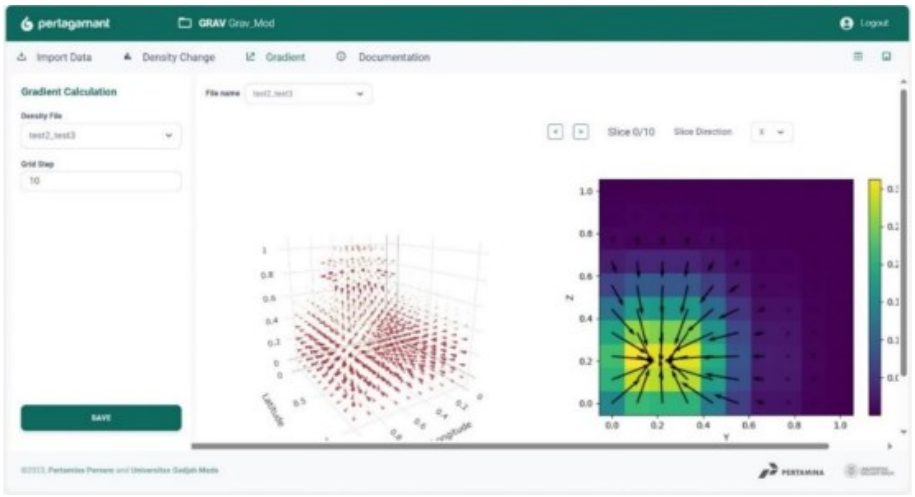

Figure 11: Simulation of gradient density from microgravity data on software PertaGAMANT.

3.3 Modul Ground Magnetic and Aeromagnetic Processing

On PertaGAMANT, we can process geomagnetic data and aeromagnetic data with flowchart below (Figure 12). The difference between ground and aeromagnetic data is located on additional correction such as effect of height variation (combination with UAV or Drone can eliminate this factor) and leveling (using micro-levelling and tie-line levelling) data (see Figure 13).

PertaGAMANT can also carry out forward and inverse modelling processes from ground and aero magnetic data to describe the initial conditions of the subsurface as an initial reference in determining reservoir boundaries along with other supporting data. An illustration of making a model based on magnetic data can be seen in Figure 15.

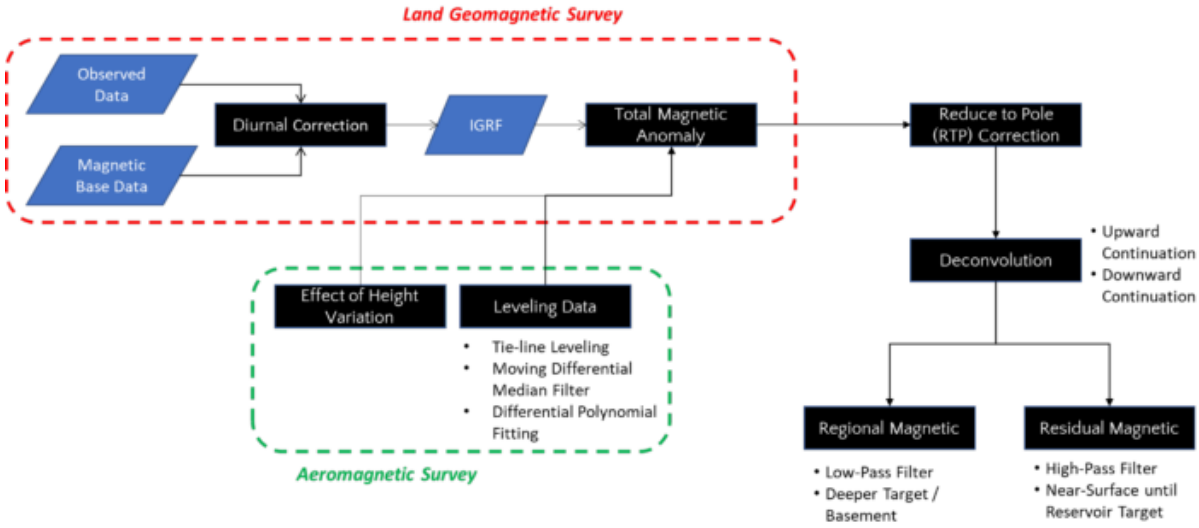

Figure 12: Flow chart to process Land Geomagnetic and Aeromagnetic Data.

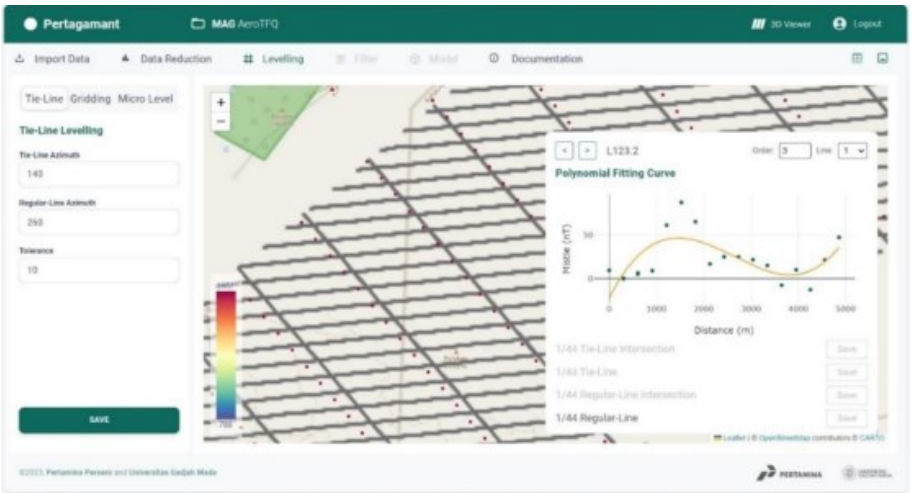

Figure 13: User Interface of software PertaGAMANT to process tie-line levelling on Aeromagnetic.

4. DISCUSSION

The conclusion from this research that:

1. PertaGAMANT software can process geoscience data in Real-Time on Cloud-Based Systems with Licensing and Log-In System Features, so users feel safe when operating this software.
2. PertaGAMANT can process geoscience data such as Ambient Noise Tomography (ANT), Spatial Auto-Correlation (SPAC), Gradient Density from Time-Lapse Microgravity Data, Ground Magnetic, and Aeromagnetic Data.

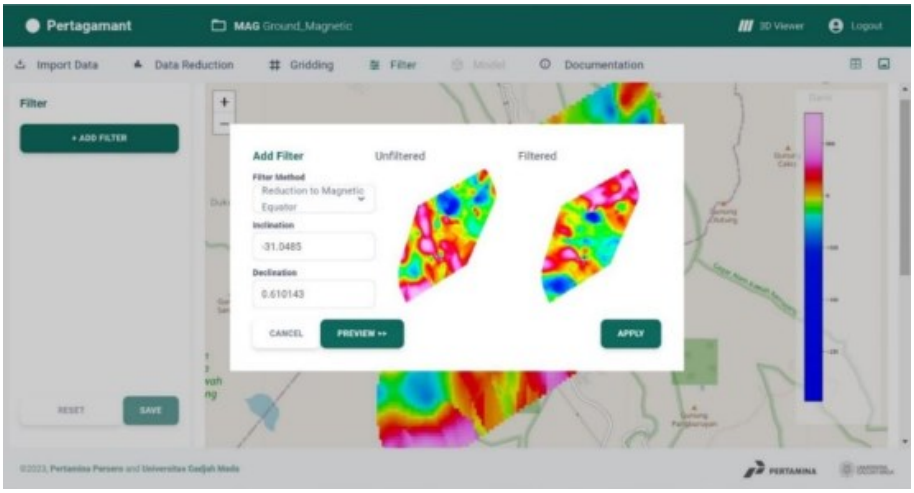

Figure 14: User Interface of software PertaGAMANT to process reduce to equator on magnetic data.

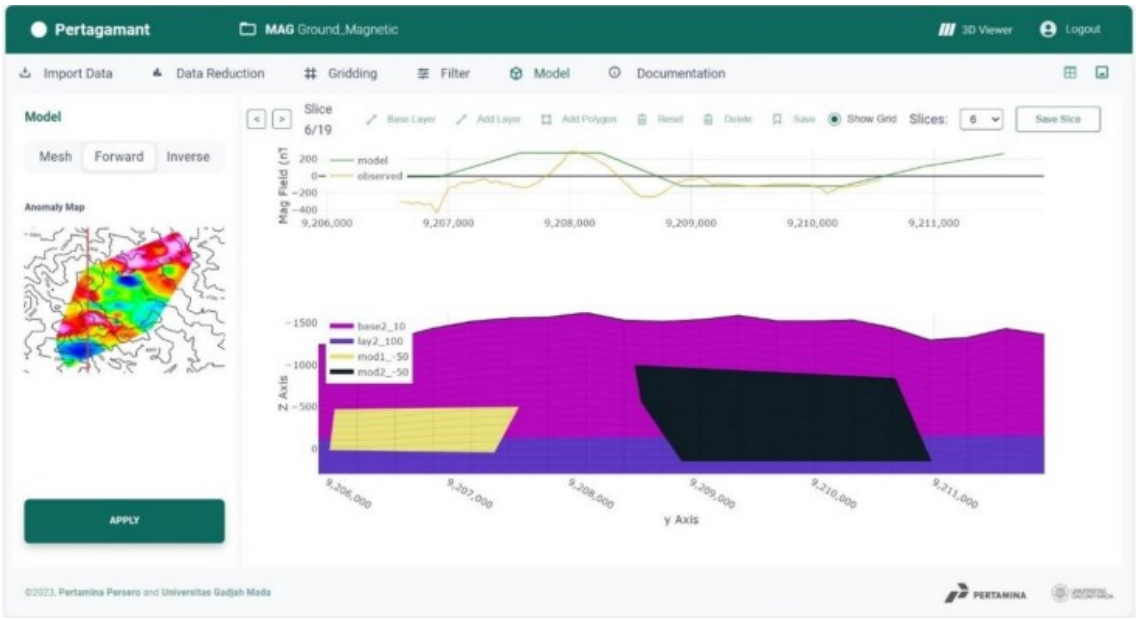

Figure 15: Example of 2D forward modelling from magnetic data on software PertaGAMANT.

ABSTRACT

The development of Indonesia's geothermal resources could be improved by enhancing the skills and expertise of its workforce. This paper looks at findings from a study by PT SMI and GRG-Geoenergis, supported by EBTKE, which suggests that better training for workers might support the initiatives to lower costs in geothermal exploration. One major issue identified is the lack of standardized certification for personnel in geothermal exploration, which may lead to less efficient operations and higher chances of project failures.

The research supports the idea of creating a national certification system specifically for the geothermal sector, along with targeted training programs. These efforts aim to improve the skills of both current and future geothermal workers, possibly leading to better project management and technical execution. The paper also explores the potential role of PPSDM KEBTKE in expanding its educational and certification services to more directly support the geothermal industry.

By making these changes, there is a chance to not only cut exploration costs but also to boost the success and sustainability of geothermal projects in Indonesia. These improvements could help build a more skilled and certified workforce, thus strengthening Indonesia's position in the global geothermal market and making better use of its vast geothermal potential.

1. INTRODUCTION

At present, Indonesia does not have a dedicated national certification scheme to verify the specialized competencies required for key personnel in geothermal exploration projects, specifically in pivotal areas like geosciences (including geology, geochemistry, and geophysics), drilling, and reservoir management. This lack of a structured certification framework poses a significant risk, as it allows for the potential involvement of individuals who may not possess the essential experience or minimum skill level required to secure the success of geothermal exploration projects. Such a scenario not only jeopardizes the project's goals but also compromises human safety, environmental sustainability, and cost-effectiveness.

In Indonesia's geothermal sector, especially during exploration, it's common for new entrants to recruit key personnel from the oil, gas, or mining industries due to perceived similarities. This trend is likely to continue as more companies unfamiliar with the unique aspects of Indonesia's geothermal environment enter the market.

Yet, geothermal resources exhibit distinct geological, geochemical, and geophysical characteristics that diverge significantly from those in oil, gas, or mining contexts. The unique challenges of geothermal exploration, such as understanding complex geothermal systems, dealing with high-temperature and corrosive fluids, and managing more variable resource parameters, requiring specific expertise and approaches.

In the absence of a national competency certification (Figure 1), individuals without geothermal backgrounds may enter key roles in geothermal exploration projects in Indonesia. Each geothermal company in Indonesia has unique recruitment procedures, which without a standardized certification, leaves room for professionals with no previous backgrounds in geothermal projects to assume critical positions.

Geothermal companies face numerous exploration challenges and must form teams with diverse backgrounds and competencies to address the risks. One of the examples is shown in Figure 2, which illustrates a typical organizational structure of a geothermal company operating drilling projects. The key personnel must manage the team from various backgrounds (and even various companies) for a safe and successful drilling operation.

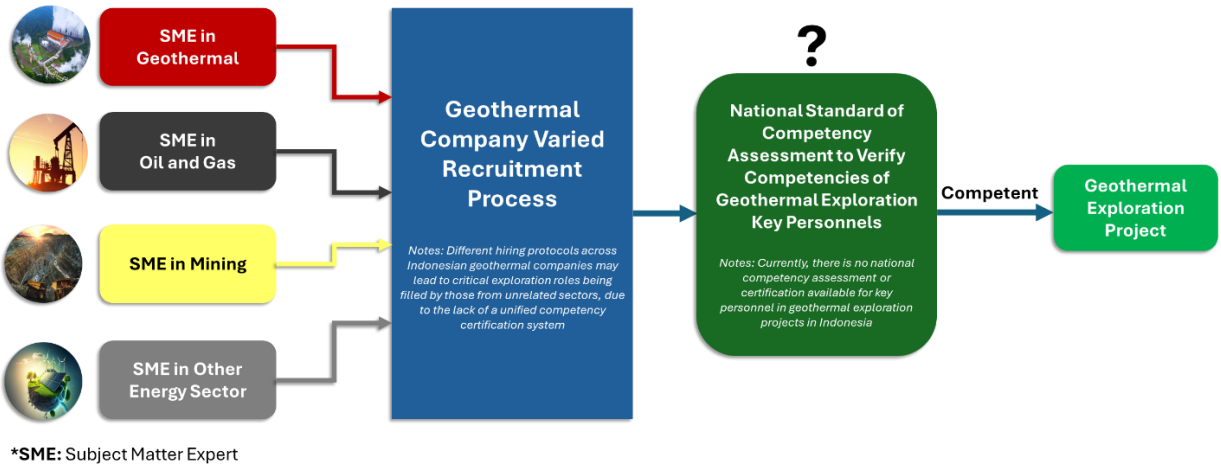

Figure 1: The current situation in Indonesia regarding the recruitment of experts or key personnel to manage exploration projects lacks a vital competency assessment process necessary to ensure project outcomes.

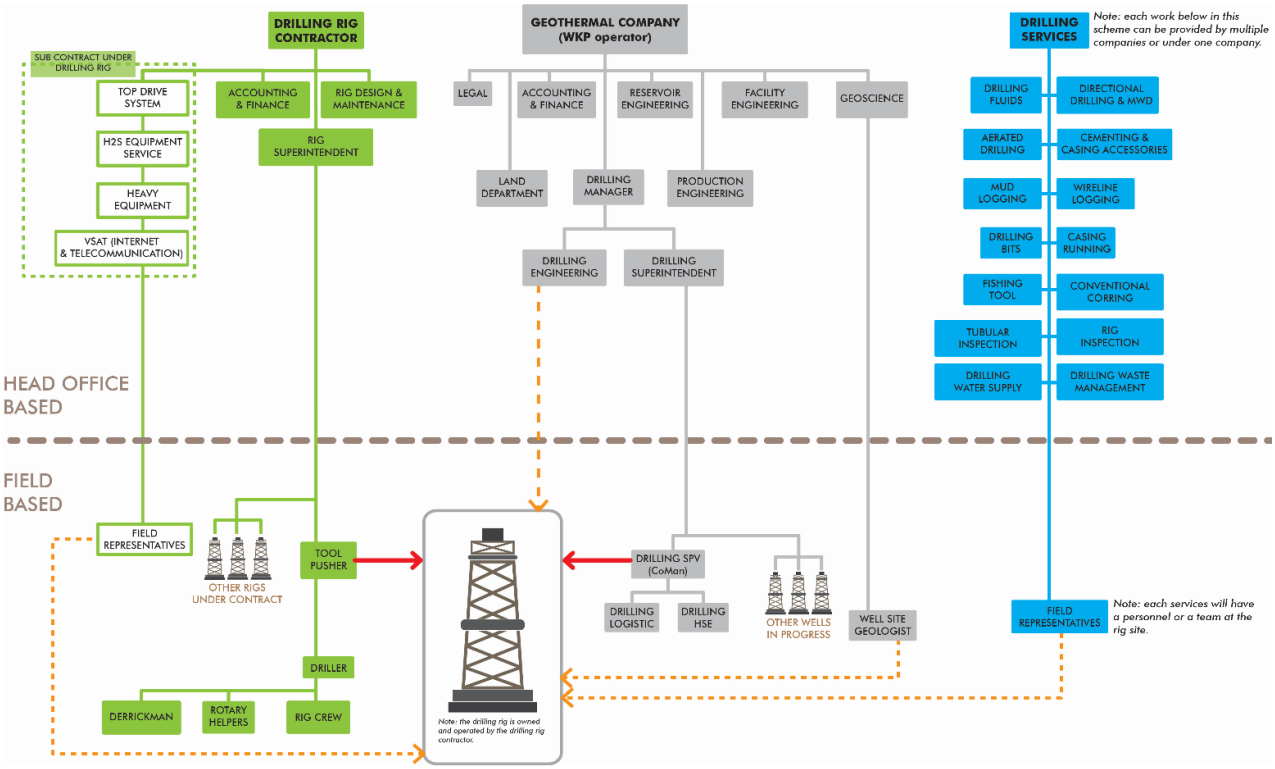

Figure 2: Typical organization structure in geothermal drilling project in Indonesia (modified from Purba et al., 2020).

2. SIGNIFICANCE OF HAVING KEY PERSONNEL WITH THE RIGHT COMPETENCIES IN GEOTHERMAL PROJECT

Given the complex and detailed nature of geothermal exploration, the lack of properly trained and experienced professionals can lead to a variety of negative outcomes, escalating both financial and operational risks:

1. **Operational Failures and Safety Incidents**: Personnel who lack experience or qualifications may not fully understand the complex geological formations involved in geothermal drilling. This can result in the use of unsuitable drilling techniques, leading to operational failures. For example, an incorrect evaluation of the pressure and temperature conditions in geothermal reservoirs might result in poorly designed wells, increasing the risk of well failures, blowouts, or even catastrophic accidents that could compromise worker safety and harm the environment.

2. **Financial Consequences**: The absence of skilled personnel carries significant financial risks. Drilling is a major expense in geothermal projects, and errors due to insufficient expertise can produce non-productive wells, requiring more investment to fix these errors or to abandon the wells completely. Drilling at incorrect locations because of inaccurate geological assessments can create dry wells that yield no geothermal fluids, thus inflating investment losses and exploration costs.
3. **Project Delays**: Inadequate expertise can significantly delay project timelines. Teams lacking the necessary qualifications might take longer to conduct drilling operations, encounter technical problems, or need multiple attempts to succeed. These delays not only increase costs but also push back the timeline for generating revenue from the geothermal resource. For instance, if a drilling team inadequately manages well casing and cementing due to a lack of knowledge about geothermal-specific practices, it might cause issues with well integrity that require extensive and costly repairs or workover.
4. **Reputational Damage**: The inability to employ skilled personnel can damage the reputation of the companies and the wider Indonesian geothermal sector. Technical failures and inefficiencies may make international investors and partners reluctant to participate in projects, leading to a decline in investor confidence and potentially hampering the sector's growth. Public incidents resulting from incompetence could foster widespread doubt and negatively impact the sector's reputation.

There is a risks associated with personnel not familiar with geothermal project. Introducing personnel from related industries who are not familiar with geothermal projects into geothermal exploration introduces considerable risks. These extend beyond operational inefficiencies to include safety issues, environmental compliance, and the financial sustainability of exploration efforts. Personnel who are not familiar with the intricacies of geothermal exploration may make strategic errors and costly mistakes that impact both immediate operations and the long-term development of the sector.

a. **Challenges with Inaccurate Well Targeting**: Precise well location targeting is crucial in geothermal exploration to effectively access heat reservoirs. This task requires a deep understanding of the geological, geochemical, and geophysical attributes of geothermal systems. Personnel from sectors like oil and gas may lack the detailed knowledge needed for successful well targeting in a geothermal setting.
b. **Overlooking Environmental and Social Impacts**: Those not familiar with geothermal exploration may not fully grasp the environmental complexities involved, nor anticipate the potential ecological impacts. This oversight can result in conflicts with protected areas, leading to environmental harm, disruptions to local ecosystems, and possible legal consequences, along with delays and extra costs for environmental mitigation and conservation.
c. **Failures in Drilling Infrastructure Construction**: Personnel inexperienced with the unique conditions of geothermal sites may struggle with setting up infrastructure in the challenging environments typical of these locations, such as areas with high-relief terrain, water scarcity, close to residential zones, or landslide-prone areas. Their lack of familiarity can cause infrastructure failures, posing safety risks and environmental issues, and leading to significant project delays and additional costs.
d. **Lack of Stuck-Pipe Prevention Measures**: The causes of stuck-pipe incidents in geothermal drilling are often different from those in oil and gas, involving specific geological challenges like fractured formations and reactive soils that are not typically found in other drilling contexts. Using inappropriate strategies can exacerbate problems, causing costly delays and equipment damage.
e. **Unsuitable Well Control Methods**: Well control practices in geothermal drilling need to address the unique properties of subsurface fluids and pressures found in these environments, which differ markedly from those in oil and gas. Conventional well control methods may not be adequate for managing the high-temperature fluids and potential phase changes encountered in geothermal wells.
f. **Increased Risk of Cost Overruns and Project Delays**: The absence of specialized expertise in geothermal exploration significantly raises the likelihood of cost overruns. This issue can manifest in various ways throughout a project's lifecycle, from poor initial planning and resource misallocation to delays in project timelines, increased chances of technical failures, and failures to meet regulatory and environmental standards.

3. LACK OF PERSONNEL COMPETENCY ASSESSMENT AND CERTIFICATION

Indonesia currently faces a significant challenge due to the absence of a formal certification system to verify the competencies of personnel in geothermal exploration. This gap allows professionals from oil, gas, and mining industries to transition into geothermal roles without fully understanding the sector's specific demands. While this cross-industry movement diversifies the talent pool, it raises concerns about project effectiveness and safety due to the lack of a dedicated competency framework for geothermal activities.

The Indonesian Ministry of Energy and Mineral Resources has established PPSDM KEBTKE, an entity tasked with delivering targeted education, training, and competency assessments to produce qualified professionals in fields such as electricity, renewable energy, and energy conservation. However, currently, PPSDM KEBTKE and the government only require safety certifications, for example, for operational supervisors. Certifications for key positions, such as geology, geochemistry, and geophysics experts at PPSDM KEBTKE, are not mandatory, which means there is no requirement for personnel to be certified in these areas. Additionally, for drilling, the only mandatory certification is well control, provided at PPSDM Migas in Cepu, Central Java. However, this well control certification primarily targets the oil and gas industry, where the mechanisms for well control and kicks differ significantly from those in geothermal drilling and can greatly impact operational safety. The full list of geothermal-related training and certification provided by PPSDM KEBTKE is shown in Table 1.

Table 1: List of geothermal-related training and certification topic conducted by PPSDM KEBTKE.

Course/Training/ Certification	Learning Method	Average Course Duration
PPSDM KEBTKE: CERTIFICATION		
Pengawas Operasional Pertama (POP) Panas Bumi	Online Training & Hybrid	5 days

*Note that the certification for specific geothermal exploration positions are only for operational supervisors and certain technical roles such as geology, geochemistry, and geophysics experts, but they are not mandatory for all key positions in geothermal exploration.

Understanding the nature of geothermal projects, which is distinct from other power generation projects (where geothermal requires exploration that may not find any resources), is also crucial. If geothermal projects, especially exploration phases, are run or led by project managers lacking sufficient knowledge, it is likely that these managers will not fully appreciate the associated risks and uncertainties. This lack of understanding can lead to inappropriate exploration strategies, making the exploration phase disproportionately expensive when uncertainties are still high.

Understanding the nature of geothermal projects, which is distinct from other power generation projects (where geothermal requires exploration that may not find any resources), is also crucial. If geothermal projects, especially exploration phases, are run or led by project managers lacking sufficient knowledge, it is likely that these managers

will not fully appreciate the associated risks and uncertainties. This lack of understanding can lead to inappropriate exploration strategies, making the exploration phase disproportionately expensive when uncertainties are still high.

Furthermore, the lack of capacity building and competency assessment threatens the future success of projects. Without adequate preparation and verification of skills, future geothermal initiatives may face escalated risks, inefficiencies, and potentially failed outcomes, undermining the sector's growth and development.

4. CURRENT AVAILABLE GEOTHERMAL TRAINING AND CERTIFICATION

4.1 New Zealand Support for Training in the Indonesian Geothermal Sector (NZSTIGS)

The New Zealand Support for Training in the Indonesian Geothermal Sector (NZSTIGS) is a collaborative effort between New Zealand and Indonesia aimed at enhancing the geothermal sector's capabilities in Indonesia through education and training (Douglas, Stuart, & Dwiyudha, 2021; Kantor Berita Antara, 2023; Umam, et al., 2021). his initiative has led to the creation of specialized training curricula and programs that are delivered to Indonesian trainers and technicians, with a strong emphasis on enhancing the skills of local personnel in both the private and public sectors of the geothermal industry.

NZSTIGS includes a variety of training programs aimed at improving skills at various levels within the geothermal industry in Indonesia. The training offered under this initiative includes:

a. Train-the-Trainer Programs: These programs are designed to provide Indonesian instructors with the skills and knowledge necessary to effectively teach geothermal technology and operations, focusing on enhancing teaching methods and practical skill application.
b. Technical Training for Operators and Technicians: Tailored courses that aim to increase the technical skills of those directly involved in the operations of geothermal plants, covering the operation and maintenance of equipment, safety protocols, and methods to optimize efficiency.
c. Capacity Building and Leadership Training: These programs focus on developing management skills and leadership capabilities among senior geothermal sector personnel, ensuring that operations are technically adept and efficiently managed.
d. Curriculum Development: This involves working with local educational institutions to develop and refine curricula tailored to the specific needs of Indonesia’s geothermal industry, ensuring alignment with current industry standards and requirements.

4.2 Other Geothermal Training, Education, and Certification in Indonesia

Beyond international collaborations, Indonesia has a range of domestic training and certification programs focused on enhancing geothermal expertise. Apart from PPSDM KEBTKE, various local institutions offer specialized training and certification in geothermal energy, as outlined below:

a. ITB Geothermal Master Program: Beyond its master’s program, the Institut Teknologi Bandung (ITB) also hosts the annual ITB International Geothermal Workshop (IIGW), which features practical field trips and post-event courses focused on topics like geothermal reservoir simulation and 3D modeling.
b. UGM – Geothermal Research Center: The Geothermal Research Center at Universitas Gadjah Mada (UGM) provides a variety of geothermal training and courses aimed at professionals and government personnel. These include professional short courses that are interactive and comprehensive, incorporating lectures, lab/field exercises, and group projects. Developed in collaboration with international institutions such as The University of Auckland and GNS Science, these courses are updated annually to reflect the changing needs of the geothermal market. UGM also offers specialized training tailored for government staff and customizable in-house training for companies, covering a wide range of geothermal development topics.
c. Enerka: Enerka delivers a diverse set of educational programs through its digital platform, designed to foster collaboration among industry professionals, students, and academics. This platform includes webinars and online courses that focus on geothermal drilling, reservoir management, and the challenges of energy transition. Enerka also offers offline training sessions conducted by experts, addressing various topics related to energy, including geothermal, to enhance skills and provide continuous learning opportunities.
d. AILIMA: Through its JIWA Learning platform, AILIMA provides a selection of online courses centered on geothermal energy, likely covering areas such as geothermal drilling, resource assessment, and wellbore simulation.

These training and certification initiatives are essential for cultivating the necessary expertise within Indonesia’s expanding geothermal sector, offering both theoretical knowledge and practical skills vital for the growth of this

renewable energy source. Additional details regarding potential geothermal education and training providers in Indonesia are shown in Table 2 and Figure 3.

Table 2: List of geothermal informal education provider in Indonesia (modified from Ayuningtyas et al., 2023).

Institution/Provider	Programs	Topics	Learning Method	Course Duration (Avg.)
PT Enerka Bhumi Pratama (ENERKA)	Free Webinar	Drilling, reservoir, production, geoscience, surface facilities, social, finance	E-Learning	1-2 hours
	Training	Drilling, reservoir, production, geoscience, surface facilities, social, finance, procurement	Online Training & Hybrid	8-12 hours
	Online Courses	Drilling, geosciences	E-Learning	10 hours
PT Anugerah Indonesia Lima (AILIMA)	Free Webinar	Drilling, Production, Reservoir	E-Learning	1-2 hours
	Online Courses	Drilling, geosciences, production, reservoir, finance	E-Learning	3 hours
Gemilang Training	Training	Introduction of Geothermal	Offline Training	2 days
PT Vyntech Multi Solutions	Training	Introduction of Geothermal	Offline & Online Training	2 days
Institut Teknologi Bandung (Geothermal Master Program)	Training	Geothermal Exploration & Development	Online	Tentative
Universitas Gadjah Mada	Training	Geothermal Exploration	Offline Training	Tentative

5. OPPORTUNITY TO OPTIMIZE PPSDM KEBTKE FOR GEOTHERMAL TRAINING AND CERTIFICATION

5.1 History of PPSDM KEBTKE

EBTKE recognizes the potential to enhance the roles of its existing training and certification bodies, such as the Center for Human Resource Development in Electricity, New Energy, Renewable Energy, and Energy Conservation (PPSDM KEBTKE). This center is primarily responsible for developing human resources in the sectors of electricity, new energy, renewable energy, and energy conservation. There is an opportunity for PPSDM KEBTKE to expand its training and certification offerings, particularly for personnel involved in Indonesia's geothermal projects.

Historically, the development of PPSDM has been in step with the introduction of Regional Autonomy, aiding developmental activities in the Energy and Mineral Resources sector. This alignment was formalized with the issuance of Presidential Decree No. 165 of 2000, establishing an Energy and Mineral Resources Education and Training Agency that included the Center for Electricity and New Renewable Energy Training (Ketenagalistrikan dan Energi Baru Terbarukan / KEBT). The formation of this institution was further detailed in the Minister of Energy and Mineral Resources Decree No. 150 of 2001 and defined by Ministerial Decree No. 30 of 2005 concerning the Organization and Work Procedure of the Ministry of Energy and Mineral Resources. Following organizational restructuring under the Regulation of the Ministry of Energy and Mineral Resources No. 18 of 2010 regarding the Organization and Work Procedure of the Ministry, the KEBT Training Center was rebranded as KEBTKE (Ketenagalistrikan, Energi Baru Terbarukan dan Konservasi Energi / Electricity, New and Renewable Energy, Energy Conservation). In 2016, with Ministerial Regulation No. 13 concerning the Organization and Work Procedure, KEBTKE was renamed PPSDM KEBTKE, tasked with the development of human resources in the specified fields.

5.2 Improvement Opportunities for PPSDM KEBTKE to Support Geothermal

As of a recent workshop held on April 30, 2024, with participation from PT SMI, EBTKE, and GRG-Geoenergis, it has been observed that PPSDM KEBTKE still offers a limited range of training and certification programs specifically for the geothermal industry. Currently, the certifications primarily focus on operational supervisor certifications (Pratama, Madya, and Utama) with an emphasis on Occupational Safety and Health to safeguard individuals and the environment during geothermal project operations in Indonesia. These certification programs for Pengawas Operasional are considered well-established and are strictly monitored by EBTKE, mandatory for the Head of Geothermal (Kepala Teknis Panas Bumi - KTPB) and recommended for several key roles in geothermal companies.

However, certifications for technical personnel, particularly in geoscience fields such as geology, geochemistry, and geophysics, are still not strictly implemented. Currently, key geoscience personnel in geothermal companies or consultants are not required to have these certifications to participate in geothermal exploration or development projects in Indonesia.

Furthermore, there appears to be a lack of alignment between the training courses and the certification list offered by PPSDM KEBTKE. Typically, individuals should undergo relevant training before attempting certification. For instance, PPSDM KEBTKE could enhance geoscience training programs to better prepare candidates for certifications in Geothermal Geology, Geochemistry, or Geophysics.

There is also a notable opportunity to expand the certification offerings for drilling personnel, considering drilling projects are major cost contributors in geothermal ventures. Ensuring that personnel managing these projects possess the necessary competencies is crucial. Currently, no certifications for drilling personnel are evident, although the training list includes a course on "Development of Plans for the Utilization and Management of Mud Waste." This course, while common in the market, seems ambiguously placed on the training list and might be more relevant for HSE drilling personnel than for drilling engineers. PPSDM KEBTKE could collaborate with the geothermal team at EBTKE to identify essential skills and competencies required for geothermal drilling personnel, such as drilling managers, engineers, superintendents, and supervisors.

6. POTENTIAL IMPLEMENTATION FRAMEWORKS FOR GEOTHERMAL CAPACITY BUILDING AND COMPETENCY ASSSESSMENT

6.1 Capacity Building and Competency Assessment Process

Capacity building and competency assessment are two interconnected processes that must continuously evolve as Indonesia develops and utilizes geothermal energy. Figure 4 illustrates a simple flowchart detailing how capacity building and competency assessment fit into the broader human resource development strategy, aimed at ensuring that key personnel are equipped to oversee geothermal exploration projects effectively in Indonesia.

Indonesia might consider two approaches Figure 4): the first scenario presumes that the proposed key personnel already meet the required competence levels, making them likely candidates to successfully complete the certification process. The second scenario, suitable for candidates with experience in the broader energy sector but lacking specialization in geothermal, suggests that they engage in a capacity-building program prior to competency assessment. This approach is not only designed to prepare them for certification but also to enhance their capabilities to manage upcoming exploration projects efficiently.

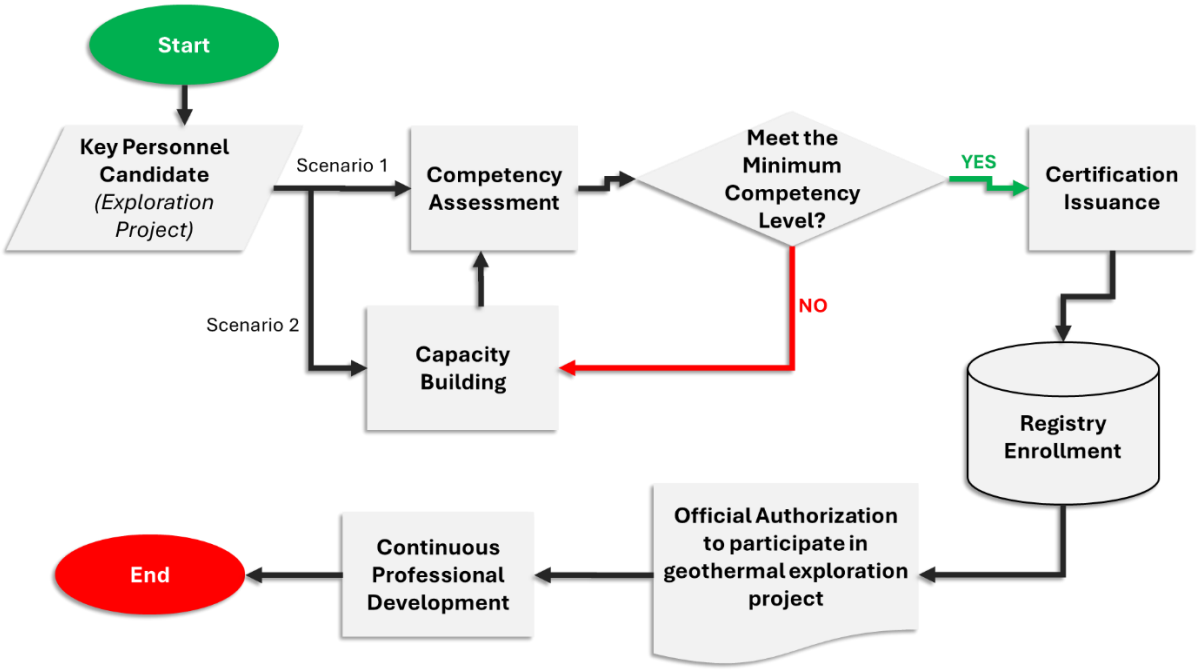

Figure 4: High-level flowchart depicting the capacity building and competency assessment process to ensure skilled management of geothermal projects in Indonesia.

When considering personnel applications, including international candidates without Indonesian certification, the following scenarios may be applied:

a. International experts are required to obtain Indonesian certification. This practice mirrors that of Indonesia's oil and gas sector, where every international expert must secure well control certification at PPSDM Migas Cepu. The certification program is offered in both Indonesian and English to accommodate international participants.
b. International experts with significant experience in Indonesia's geothermal sector or who have attained a certain educational level in geothermal studies might be considered as alternatives to undergoing certification.

The specifics of this mechanism will be further developed by a task force charged with shaping the certification program.

6.2 Proposed Implementation Framework

To outline the path forward for the Indonesian Government in addressing these Policy Opportunities, this sub-chapter proposes an Implementation Framework. This framework is designed to bolster the competencies of Indonesia's geothermal workforce and provides a structured roadmap for the government to effectively implement policy recommendations:

1. Establish a cross-sectoral task force:
    a. Form a task force with representatives from the Ministry of Energy, educational institutions, industry associations, and international experts to oversee policy implementation.
    b. The task force's main function would be to coordinate activities, track progress, and align initiatives with strategic national energy objectives.
    c. The urgency and focus of this task force are crucial for catalyzing immediate progress.
2. Develop and approve competency standards:
    a. Collaborate with international experts to establish competency standards for key geothermal roles that reflect both local requirements and global best practices.

   b. Organize a thorough review and approval process with multi-sectoral stakeholder involvement to ensure broad industry support and government ratification.
   c. Promptly allocate funding and initiate program development to meet current and future competency needs in the sector.

3. Establish certification and accreditation bodies, or utilize the existing bodies (BNSP):
   a. Designate authoritative bodies to manage the certification process, equipped with the necessary expertise and resources.
   b. Develop accreditation criteria for training programs to maintain consistency and quality across educational and professional development initiatives.
   c. Engage potential certification partners listed in Table 2 and Figure 3, positioning PPSDM KEBTKE as a potential leader under EBTKE supervision.

4. Roll out training and certification program:
   a. Launch targeted training programs to address identified competency gaps, utilizing both local and international resources.
   b. Introduce a certification process that is accessible and mandatory for key personnel in the geothermal sector, with potential providers as shown in Table 2 and Figure 3.

5. Foster industry-academia partnership:
   a. Promote collaborations between geothermal companies and educational institutions to tailor academic programs to industry needs and provide practical experience.
   b. Support joint R&D projects that focus on cutting-edge geothermal technologies and methods.

6. Monitor, evaluate, and iterate:
   a. Set up systems for continuous monitoring and evaluation of the implementation process, using performance indicators to measure progress and impact.
   b. Regularly refine competency standards and training programs based on feedback, technological advancements, and changing industry demands.

As an initial action, the Government of Indonesia could expand PPSDM KEBTKE's certification offerings to include specialized programs across various geothermal disciplines such as exploration, geoscience, drilling, reservoir, and power plant management. This expansion would not only enhance the competency of the geothermal workforce but also position PPSDM KEBTKE as a leader in capacity building and competency assessment within Indonesia's geothermal industry, laying a strong foundation for sectoral growth.

ABSTRACT

In Indonesia, assessing drilling costs and performance is challenging due to the absence of a centralized geothermal drilling database. This stands in contrast to the oil and gas sector, which benefits from established databases like IHS Rushmore. The lack of similar resources in the geothermal sector underscores the need for a more structured approach to data collection and management to better inform decisions and improve operational efficiencies.

This study proposes adopting models like IHS Rushmore from the oil and gas industry, which promote standardized data collection and transparent operational insights. By requiring systematic data submission and encouraging data sharing, this framework aims to improve planning accuracy, reduce drilling costs, and facilitate smoother project execution.

Implementing this system would involve establishing a robust regulatory framework for mandatory data sharing, as well as developing a digital platform accessible to government agencies, developers, and researchers. This platform would enable real-time data analysis, supporting proactive adjustments in drilling operations and strategic decision-making. Furthermore, the database is envisioned as an essential tool for capacity building among governmental bodies and stakeholders, thereby enhancing Indonesia's competitiveness in the global geothermal market.

1. INTRODUCTION

1.1 Geothermal Development Challenges in Indonesia

Indonesia possesses approximately 40% of the world's geothermal reserves, making it one of the most promising countries globally for geothermal energy, with an estimated potential of around 18,000 megawatts (MWe). Despite this significant potential, only about 13% of it is currently utilized, translating to an installed capacity of 2,356 MWe (ThinkGeoEnergy, 2023). This utilization rate is comparatively low when measured against countries like New Zealand, which uses 38% of its potential, and the United States, which utilizes 21% (Asokawaty et al., 2020). To improve this rate, the Government of Indonesia (GoI) aims to achieve 5,486 MWe of geothermal power plant installations by 2030 (Direktorat Panas Bumi, 2022).

Numerous studies and papers have outlined the various challenges faced by the Indonesian government and geothermal developers in advancing geothermal projects (Ibrahim et al., 2005; IGA, 2014; Poernomo, 2015; Darma, 2016; Purba, 2018; Umam et al., 2018; Purba et al., 2019; Purba et al., 2020a; Utami, 2010; Purba et al., 2021a). The exploration phase stands out as the most critical stage in achieving the national geothermal targets.

Achieving Indonesia's geothermal energy goals necessitates collaboration among all stakeholders, including government bodies, geothermal development companies, investors, off-takers, academics, researchers, local communities, and various institutions involved in these projects.

The primary challenges in developing geothermal energy in Indonesia stem from two main factors:

1. The high level of uncertainty about the presence of economically viable geothermal resources (resource risk).
2. The substantial costs associated with drilling activities required to confirm these resources.

Geothermal drilling is widely recognized as a complex and expensive endeavor due to subsurface uncertainties, surface-level challenges, and the involvement of multiple stakeholders, organizations, and equipment (Bodley, 2018; Gul and Aslanoglu, 2018). Poor project management can lead to project failures (Discenza and Forman,

2007). Experts such as Southon and Gorbachev (2003), Kipsang (2015), Bodley (2018), and Otieno (2016) emphasize the critical importance of the planning phase and a thorough understanding of all drilling activities to manage costs effectively. Additionally, Hole (2008) categorizes the cost-driving factors into those that are beyond control and those that can be managed.

1.2 Geothermal Drilling Cost in Indonesia

Geothermal drilling represents a significant portion of total project costs, influenced by geological complexity, drilling depth, and the availability of infrastructure and expertise. Indonesia's geothermal drilling costs are among the highest in the world, primarily due to challenging geological conditions and inadequate local infrastructure for deep drilling operations.

These high drilling costs impact both the economic viability and the overall pace of geothermal development in Indonesia. Reducing these costs through improved efficiency, technology, and data analysis is essential for accelerating geothermal energy development. Given Indonesia's substantial geothermal energy potential, understanding the dynamics of drilling costs is crucial. This section compares Indonesia's geothermal drilling costs with global practices to identify actionable insights for cost optimization.

1.2.1 Global Context of Geothermal Drilling Cost

Geothermal drilling costs vary widely across the globe due to geological, geographical, and market factors. Countries like the Philippines and Indonesia face some of the highest drilling costs per meter, largely due to challenging geological conditions and less developed local supply chains. These variations highlight the need for context-specific cost management strategies and a detailed understanding of each country's unique challenges.

Figure 1 summarizes average drilling costs per meter for geothermal wells in various countries. The Philippines has the highest drilling cost at 4586 USD per meter, followed by Indonesia at 3432 USD per meter. The USA ranks third at 3032 USD per meter. Kenya's costs are 2667 USD per meter, while New Zealand and Iceland have lower costs at 2597 USD and 2376 USD per meter, respectively.

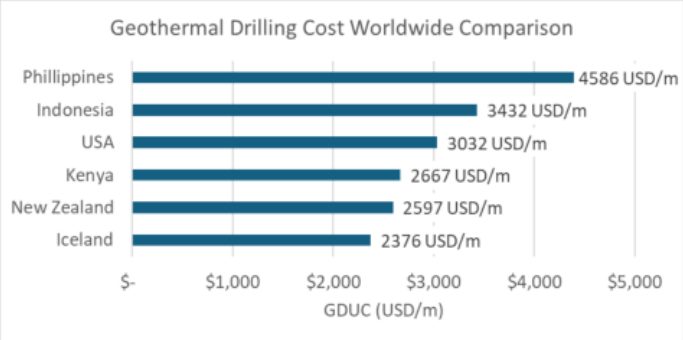

Figure 1: Bar Chart of Average Geothermal Drilling Cost Worldwide (GRG-Geoenergis, 2024).

1.2.2 Indonesia Geothermal Drilling Cost Landscape

In Indonesia, high geothermal drilling costs are driven by well depth, geological complexity, and logistical challenges. Costs increase with well depth due to higher complexity and risk. This relationship underscores the critical nature of well depth in drilling operations.

Geothermal Drilling Unit Cost (GDUC), proposed by Zuhro and Arif (2015), measures drilling performance in USD per meter, allowing cost comparison between wells of different depths. Figure 2 illustrates the GDUC distribution in Indonesia, ranging from 1,300 to 22,000 USD per meter per well. Wells exceeding 7,000 USD per meter are rare outliers. Using the median as a more stable measure, typical drilling costs in Indonesia fall within the interquartile range of 2,733 to 4,549 USD per meter, with a median of 3,432 USD per meter.

The varied well depths in Indonesia reflect a complex drilling landscape where decisions on well depth must balance technical requirements and cost implications. The significant variability in costs highlights diverse operational efficiencies and geological challenges across projects.

Geological hazards, particularly stuck-pipe incidents, contribute to high drilling costs. A PT SMI (2023) study shows these incidents can triple normal drilling costs. Table 1 details the highest drilling costs in Indonesia, with the most expensive well at 29.4 million USD for a 2,160-meter depth, which was non-productive. High costs were largely due to 311.5 hours of Non-Productive Time (NPT) caused by stuck pipes, constituting 27% of the drilling duration and leading to cost overruns. Similar incidents caused the second and third highest costs of 28.4 million USD and 24.1 million USD, respectively.

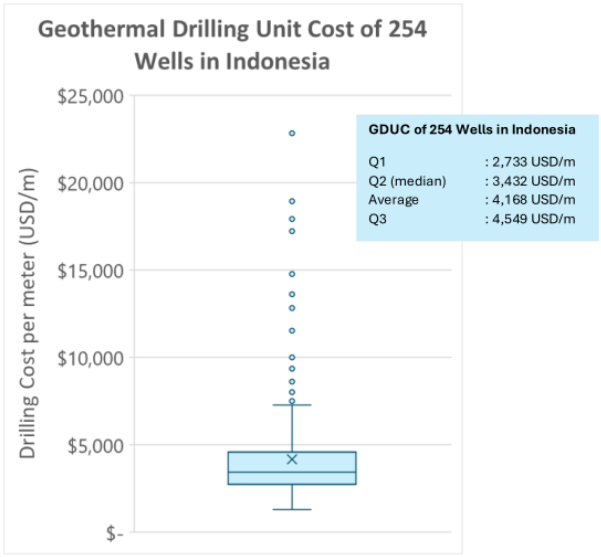

Figure 2: Box Plot of Geothermal Drilling Unit Cost in Indonesia (GRG-Geoenergis, 2024).

Table 1: Outlier Data of the Highest Drilling Cost in Indonesia (GRG-Geoenergis, 2024).

No	Well Name (De-identified)	Well Location	Well Depth (mMD)	Total Drilling Cost (USD)	Drilling Cost per meter (USD/m)	Well Status
1	Highest Well Cost-1	Sumatra	2,160	$29,408,487	$13,615	Non-productive
2	Highest Well Cost-2	Sumatra	1,654	$28,441,465	$17,196	Non-productive
3	Highest Well Cost-3	Sumatra	2,941	$24,110,166	$8,198	Productive
4	Highest Well Cost-4	East Java	2,770	$22,904,286	$8,269	Productive
5	Highest Well Cost-5	Sumatra	3,014	$21,352,215	$7,084	Productive
6	Highest Well Cost-6	Sumatra	2,272	$19,824,782	$8,725	Non-productive
7	Highest Well Cost-7	Sumatra	3,006	$17,559,075	$5,841	Productive
8	Highest Well Cost-8	Sumatra	1,503	$17,335,170	$11,534	Non-productive
9	Highest Well Cost-9	Sumatra	1,253	$17,323,032	$13,825	Non-productive
10	Highest Well Cost-10	Sumatra	2,133	$15,988,860	$7,494	Non-productive
11	Highest Well Cost-11	Sumatra	1,829	$15,938,855	$8,716	Non-productive
12	Highest Well Cost-12	Sumatra	1,668	$15,605,100	$9,356	Productive
13	Highest Well Cost-13	Sumatra	2,500	$15,563,587	$6,225	Non-productive

This data underscores the high-risk nature of geothermal drilling in Indonesia, frequently encountering substantial cost overruns and the risk of no steam production. Preventing stuck-pipe incidents is crucial to managing costs in geothermal projects.

1.3 Problem Statement and Findings

Indonesia holds about 40% of the world's geothermal reserves, with an estimated potential of 18,000 megawatts (MWe). However, only 13% of this potential is currently utilized. High geothermal drilling costs, driven by geological complexity, well depth, and logistical challenges, hinder the economic viability and pace of development. These costs are among the highest globally, worsened by the lack of a standardized, integrated drilling database, which hold back effective cost analysis, strategic planning, and operational efficiency.

There are two significant gaps that geothermal stakeholders in Indonesia need to address for drilling cost optimization:

1. *Lack of Integrated Database and Standardization*: Indonesia's geothermal sector lacks a centralized, integrated database to compile and standardize drilling data across various projects and locations. This absence hinders effective cost analysis, obscures sector-wide performance metrics, and impedes the identification of cost-saving opportunities. Without standardized costing structures, benchmarking against both national and international standards become inaccurate and inefficient.
2. *Data Confidentiality and Publication Scarcity*: The confidential nature of drilling data complicates the landscape, as developers often hesitate to share data due to competitive concerns or proprietary considerations. This results in a scarcity of publicly available information. Additionally, the lack of comprehensive publications on geothermal drilling costs limits the sector's access to valuable insights and learnings. Existing reports often lack detailed cost breakdowns, failing to provide a robust foundation for thorough analysis and informed decision-making.

Drilling constitutes a major portion of the overall cost in geothermal projects, and its optimization is crucial given the high risks associated with operational uncertainties The absence of a centralized database prevents benchmarking, cost optimization, and knowledge sharing among developers, further stalled by the confidential nature of existing data. Geological hazards like stuck-pipe incidents lead to significant cost overruns, underscoring the need for robust data to improve drilling practices and risk management.

To overcome these challenges, a comprehensive framework for geothermal drilling data integration is essential. Establishing a centralized, accessible database will facilitate detailed cost analysis, enhance efficiency through data-driven insights, and promote transparency and collaboration among stakeholders, thereby accelerating the utilization of Indonesia's geothermal potential.

1.4 Study Objectives

This study aims to offer actionable recommendations for establishing standardized regulations for the collection and management of geothermal drilling data. Standardizing these practices will increase data accessibility and transparency, aligning Indonesia with global data management standards such as the IHS Rushmore platform. This alignment will enhance project planning, reduce costs, and improve competitiveness in the global geothermal energy market.

2. ENHANCING DRILLING EFFICIENCY WITH STRATEGIC DATA MANAGEMENT

2.1 Differentiating Data, Information, and Knowledge

Adityatama et al. (2021) provide insights into the definition of data, highlighting that its meaning can vary depending on the source or context. Essentially, data consists of facts, numbers, or other entities that, in isolation, lack context or purpose. To become useful, data must be organized into a coherent format, transforming it into information. This information can then be interpreted, analyzed, and utilized for various purposes such as decision-making and evaluation, thereby evolving into knowledge, as depicted in Figure 3. Without systematic organization into databases or documents, data remains practically unusable.

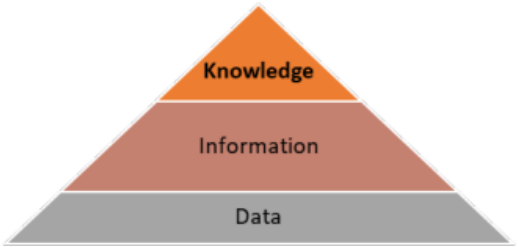

Figure 3: Illustration of data, information, and knowledge (modified from Damski, 2014).

Oracle (2019) defines data management as "the practice of collecting, keeping, and using data efficiently and cost-effectively." However, the scope of data management in drilling operations often remains ambiguous. Some might consider streaming real-time mud logging data from a drilling site to headquarters or storing various data types on company servers as sufficient forms of data management. Damski (2014), however, argues that such practices are insufficient from a business standpoint, as they incur costs without direct returns on investment (ROI). True value from data management emerges only when the information derived from the data informs decisions that enhance the company's business processes, thereby justifying the initial investment.

Moreover, the potential for business intelligence relies on data being readily available and accessible. When data is processed and accessible, the quality of business intelligence or data interpretation can lead to improved drilling programs and more accurate drilling cost estimations. However, learning from past drilling operations is often compromised by the lack of a robust database or data management system, which discourages engineers from

seeking out valuable data. According to Johnson (2002) and Sokovic, Pavletic, & Pipan (2010), the PDCA (Plan, Do, Check, Act) cycle is a vital approach to quality management and continuous improvement in capturing and leveraging drilling data across all stages of a well's lifecycle.

Figure 4: Optimizing Drilling Operations - Leveraging the Lessons Learned Cycle from Historical Drilling Data (Adityatama et al., 2021).

2.2 Utilizing the Lessons Learned Cycle from Historical Drilling Data

Drilling represents a significant portion of the overall costs in geothermal projects, making its optimization crucial due to the high risks associated with operational uncertainties. Enhancing the planning and execution of drilling operations through detailed analysis of historical drilling data is essential (Figure 4).

However, as Iyoho et al. (2004) point out, such analysis is often not conducted as rigorously as it should be. A significant barrier to consistent drilling analysis is the lack of a comprehensive knowledge-based data management system that can effectively integrate and analyze relevant drilling and geological data.

The issue of knowledge retention in the oil and gas industry, particularly within drilling operations, is significant (Sumbal, Tsui, See-to, & Barendrecht, 2017). There exists a notable generation gap among drilling engineers, underscoring the necessity of documenting lessons learned and ensuring knowledge transfer between generations (Damski, 2014). Given these challenges in a well-established sector like oil and gas, it is reasonable to anticipate similar issues in the less-developed geothermal industry. Without detailed records of lessons learned, process descriptions, field knowledge, and comprehensive analyses of previous drilling operations, optimizing or enhancing future drilling plans in the geothermal sector will be challenging, if not unfeasible.

2.3 Learning Curve in Geothermal Drilling

In geothermal drilling, new fields often show less efficient performance, with longer drilling durations, increased Non-Productive Time (NPT), and higher costs. This inefficiency usually decreases as operations continue. The learning curve concept varies significantly by site and operator. Expertise and experience from one location may not transfer effectively to another, even with the same operator. This is especially true when drilling extends to new or unexplored areas with unexpected challenges.

Figure 5 illustrates this pattern at Pertamina Geothermal Energy (PGE) from 2007 to 2011, where an upward trend in the rate of well completion (ROWC) shows growing efficiency. However, the ROWC dropped between 2012 and 2013 due to expansion into new areas and using an unfamiliar contractor.

Understanding the learning curve is crucial for reducing drilling costs. Familiarity with the team's capabilities and equipment, combined with insights from previous drilling in the same area, can reduce NPT, leading to better performance and cost optimization.

2.4 What Is Non-Productive Time (NPT)?

GRG-Geoenergis (2024) defines Non-Productive Time (NPT) as periods when drilling operations are unexpectedly halted or when drilling rates are critically low (Emhanna, 2018). NPT not only affects the timeline but also significantly increases operational costs, making the reduction of NPT crucial for enhancing drilling efficiency and reducing expenses. Originating in the 1960s, various studies and methodologies have since been developed to manage and minimize NPT to acceptable levels (Barakat, et al., 2021). NPT is a primary factor in project delays and cost overruns in drilling projects due to standby charges and penalties related to equipment and personnel (Hsieh, 2010). Figure 6 illustrates a typical NPT breakdown, commonly included in the Final Well Report or End of Well Report.

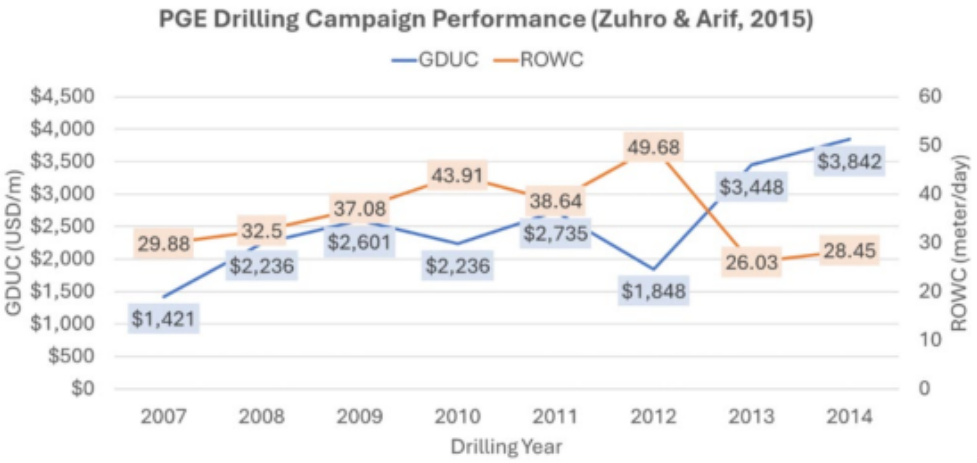

Figure 5: PGE Drilling Campaign Performance (Zuhro & Arif, 2015).

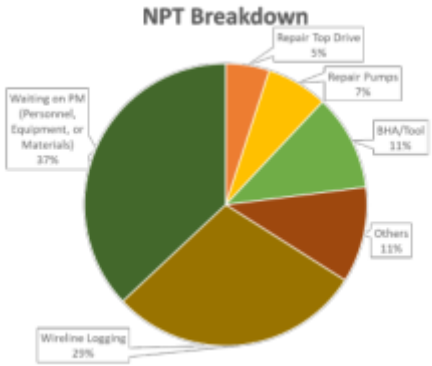

Figure 6: Example of NPT Breakdown in one of Geothermal Field in Indonesia (GRG-Geoenergis, 2024).

Interviews conducted by GRG-Geoenergis (2024) revealed that the highest drilling costs in Indonesia were primarily due to repeated stuck pipe incidents. One well experienced 311.5 hours of Non-Productive Time (NPT), constituting 27% of the total drilling duration, significantly extending the schedule and causing substantial cost overruns. Similar issues contributed to the second and third most expensive wells, costing 28.4 million USD and 24.1 million USD, respectively. These frequent occurrences underscore the inherent risks and high costs in geothermal drilling, highlighting the urgent need for effective stuck pipe prevention strategies to minimize financial losses and improve operational efficiency.

2.5 Potential Problems of Lacking a Standardized Geothermal Drilling Database in Indonesia

The absence of a standardized geothermal drilling database in Indonesia presents several significant potential problems:

1. *Inefficient Cost Management*: Without a centralized database, accurate cost analysis and benchmarking are difficult, leading to higher exploration and development costs as opportunities for cost reduction are harder to identify and implement.
2. *Limited Benchmarking Capabilities*: The lack of standardized and accessible data makes it problematic to compare performance, costs, and best practices across different projects or against international standards, limiting the ability to learn from past projects and improve future operations.
3. *Impaired Strategic Planning*: Strategic decision-making relies heavily on robust data. The absence of a comprehensive database hinders effective planning by the government and developers, potentially delaying new projects and the optimization of existing ones.
4. *Barrier to Research and Development*: Researchers and developers need detailed historical data to innovate and improve geothermal drilling technologies. Without access to such data, the pace of technological advancement and environmental studies in the geothermal sector may slow down.
5. *Regulatory and Policy Challenges*: The government's ability to formulate and enforce regulations that promote efficient and environmentally sustainable geothermal development is compromised without detailed and reliable data.

6. *Transparency and Accountability Issues*: A comprehensive database would enhance transparency by making information available to all stakeholders, including the public. Its absence can lead to accountability issues, making it difficult to trace problems or inefficiencies back to their sources.
7. *Competitive Disadvantage*: On an international scale, the lack of a centralized data system can place Indonesia at a competitive disadvantage compared to countries with robust data infrastructures, potentially affecting foreign investment and collaboration opportunities in the geothermal sector.

2.6 IHS Rushmore: An Oil and Gas Industry Standard in Peer-To-Peer Performance Data Sharing

IHS Markit's Rushmore Reviews, known as IHS Rushmore, is a leading service in the oil and gas industry, offering benchmarking and analysis. Its Drilling Performance Review (DPR) is a global platform, used by over 170 operators from 100 countries for sharing and analyzing drilling data. Known for its accuracy and independent quality control, the DPR includes around 120 data fields. It offers metrics, charting options, and tools like the Rushmore Estimated Drilling Days (REDD) and Rushmore Drilling Index (RDI), covering aspects such as:

1. Well identification.
2. Drilling technical details and methods.
3. Drilling fluid and coring / logging.
4. Hole size, mud, and casings.
5. Time durations including Non-Productive Time (NPT).
6. NPT codes.
7. Costs.
8. Time-depth chart.

The IHS Markit Rushmore Drilling Database (Figure 7) functions as a collaborative, data-driven tool that helps oil and gas companies benchmark their performance, gain insights into industry trends, and make informed decisions to optimize their drilling and completion operations. It has been proven to enhance operational efficiency and strategic planning with its comprehensive data and insights.

Figure 7: Snippet of IHS Rushmore Dashboard (S&P Global, 2022).

3. ESTABLISHING INDONESIA'S GEOTHERMAL DRILLING DATA SYSTEM

3.1 Analyzing the Current State of Indonesia's Geothermal Drilling Costs and Performance

In the pursuit of establishing a standardized framework for geothermal drilling cost structure and performance reporting in Indonesia, it is imperative to scrutinize the prevailing impediments that hinder process efficiency and industry transparency. Several challenges that currently faced by Government of Indonesia (GoI) and related stakeholders for developing drilling database is summarized as follows:

a. The Drilling cost reports submitted by developers have Various Format.
Based on discussion with EBTKE, the format of drilling cost reports/structures submitted by developers to EBTKE is varied. Some cost reports combine several cost/line items, complicating the input into drilling cost databases and hindering consistent, apple-to-apple cost comparisons.

b. Benchmarking and Lesson Learn Extraction Might be Challenging.
The heterogeneity of report formats further presents a challenge in the extraction of lessons learned and the establishment of industry-wide benchmarks. The capacity for a sector to evolve and optimize is contingent upon the systematic collation and analysis of historical data. Due to these inconsistencies in cost reporting, extracting lessons learned or identifying optimal practices by apple-to-apple comparison is more challenging.

c. Lack of a Standardized Costing Structure for Geothermal Drilling in Indonesia.
Indonesia currently doesn't have a standardized way of breaking down the costs of geothermal drilling. Currently, there is no regulation or policy that obligates developers to use a uniform/standard format for submitting drilling cost reports to EBTKE. Unlike the oil and gas sector in Indonesia, which benefits from established Budget Schedules (BS) 19 and 20 as provided and enforced by SKK Migas, the geothermal industry currently lacks a standardized cost structure for drilling. This absence of standardization not only hinders accurate cost estimation for future projects but also complicates comprehensive cost evaluations and analyses. Moreover, not all the BS-19 and BS-20-line item can be applicable with geothermal drilling project. Without a uniform costing framework that is enforced by the government, developers will most likely use their own cost structures when reporting to the government, leading to challenges in comparing costs and performance across various projects from different companies in Indonesia. A consistent framework would enable a detailed breakdown of various costs such as rig and equipment expenses, supporting services, materials, labor, and infrastructure. This level of detail is vital for optimizing costs, effectively managing risks, and developing a more accurate cost estimate. It also facilitates prudent resource allocation and allows for benchmarking against industry standards, which is essential for maintaining project viability and competitiveness.

d. Absence of Obligatory Policy for Cost and Performance Reporting in Geothermal Drilling.
Though the Directorate General of New, Renewable Energy, and Energy Conservation (EBTKE) has recommended the adoption of BS-19 and BS-20 standards for geothermal drilling, developers have not uniformly followed these guidelines. This indicates an absence of obligatory policy or regulation governing such standardizations of cost reporting within the geothermal sector. Additionally, align with WB's concern that not only drilling performance reporting is required to be submitted by geothermal developer, but also it requires to submit supporting information such as well pressure and temperature (P&T) and well output

3.2 Adopting Drilling Cost Reporting Format from Indonesia's Oil and Gas Industry

Indonesia has established standard costing for oil and gas drilling, detailed in Budget Schedules (BS) 19 and 20, as regulated in document PTK-063/SKKMA0000/2017/S (SKK Migas, 2017). These reports are specifically utilized for documenting and reporting drilling costs by the Cooperation Contract Contractors (KKKS) to the Special Task Force for Upstream Oil and Gas Business Activities (SKK Migas). These formats are crucial to the industry's cost recovery mechanism, allowing KKKS to be reimbursed for operational costs incurred in upstream oil and gas activities. Utilization of BS 19 and BS 20 is explained as follow:

1. BS 19 (Budget Schedule 19): This schedule is used to report both tangible and intangible costs associated with drilling, workover, or well services in oil and gas operations. It includes a wide array of costs such as:
    a. Tangible Costs: Expenses on physical items like casing, casing accessories, tubing, and surface and subsurface well equipment.
    b. Intangible Costs: Costs related to non-physical aspects such as drilling preparation and termination, drilling service operations, formation evaluation, completion, and general expenses like project management, permits, and overhead costs.
2. BS 20 (Budget Schedule 20): This schedule complements BS 19 by detailing the material lists that constitute the tangible and intangible costs reported in BS 19. Essentially, BS 20 provides a breakdown of the components that make up the total drilling costs.

These schedules are instrumental in maintaining transparency and accountability in financial reporting within Indonesia's oil and gas sector. By standardizing the cost reporting process, BS 19 and BS 20 ensure that all relevant expenses are duly recorded and reported, facilitating the cost recovery process, and aiding in the efficient financial management of upstream oil and gas activities. Figure 8 show the snippets of BS 19 and BS 20 used in the Indonesian oil and gas industry.

Currently, EBTKE, as the Indonesian government's representative in regulating the geothermal industry, has advised developers to adopt the BS 19 and BS 20 forms from the oil and gas industry for reporting drilling costs, both in the planning and realization stages. However, as discussed in previous sub-section, interviews with EBTKE reveal that not all developers use or submit drilling costs using these formats. One reason EBTKE cannot enforce this practice is that, unlike the oil and gas industry, the geothermal industry in Indonesia does not operate on a cost recovery scheme. In the case of SKK Migas, if an oil company fails to submit cost reports in the prescribed format, SKK Migas has the authority to reject the company's cost recovery requests.

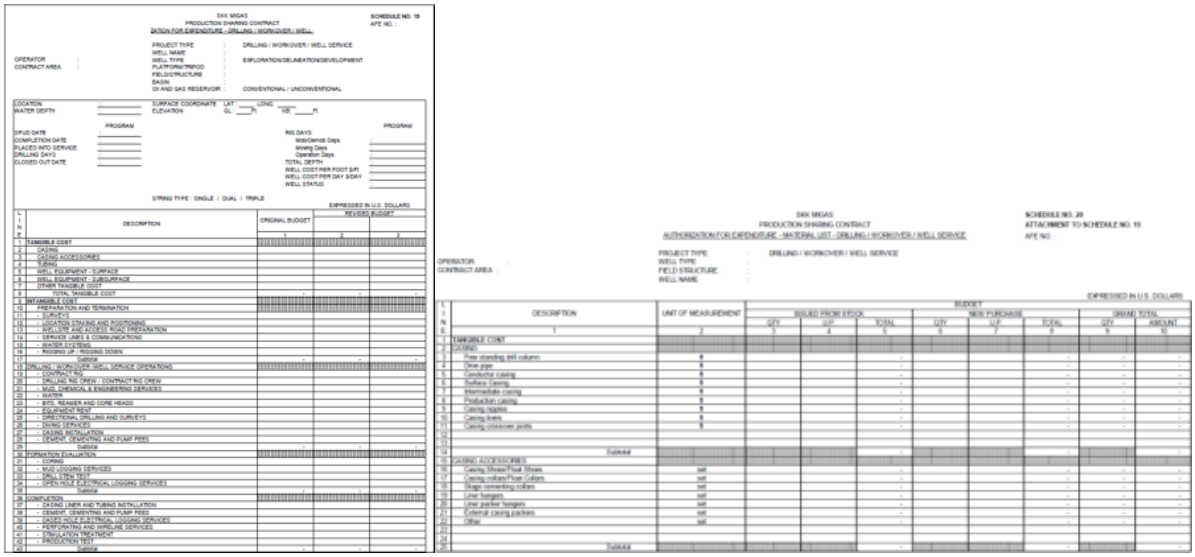

Figure 8: Snippet of Budget Schedule and Report 19 (BS 19) (left) and Budget Schedule and Report 20 (BS 20) (right) (SKK Migas, 2017).

Subsequently, the standard of drilling costing structure of Indonesia's geothermal industry is synthesized according to the geothermal drilling cost components that illustrated in Appendix 1. Proposed Geothermal Drilling Cost Structure Reporting The proposed geothermal drilling cost reporting form is derived from the BS 19 and B20 in the oil and gas industry, the geothermal drilling cost components that have been identified in this study, drilling cost reporting experience from several geothermal developers in Indonesia, and EBTKE's work and budget plan.

3.3 Adopting Drilling Performance Reporting Format from Indonesia's Oil and Gas Industry

In oil and gas industry, after the well is already completely drilled and tested, the oil and gas companies usually are obligated to submit several documents to Special Task Force for Upstream Oil and Gas Business Activities (SKK Migas) for project close-out.

Based on Interview with oil and gas developer company, several drilling-related documents that are obligated to be submitted to SKK Migas after well completely drilled are as follows:

1. End of Well Report (EOWR) / Final Well Report (FWR)
2. Well Post Mortem (excel and pdf document)
   The well memo/postmortem report generally contains the well basic information (well name, AFE number, rig used, spud and complete date, total drilling days, well depth plan vs actual, total planned vs realization well cost), casing program vs actual, time distribution summary, well operation summary, well schematic and completion diagram).
3. Well Form 19-I (excel and pdf document)
   Several contents of this document are like well memo / postmortem report. The Well Form 19-I is the complete version of postmortem report. This document contains such as the breakdown of drilling times (moving days, operation days, and completion days), rig contract name, well cost per foot ($/ft), well cost per day ($/day), breakdown of planned and actual well cost (tangible and intangible cost), summary of bit record, summary of drilling fluid and cement record, well equipment surface and subsurface information, summary of logging tools used and result, documentation of wellhead after completion, non-productive time (NPT) analysis and budget impact, also program changes during operation and budget impact.
4. Recapitulation of Daily Drilling Report (DDR) (excel and pdf document).
5. Final Time Distribution (Final Time Vs Depth Vs Cost) (excel and pdf document).
6. Budget and Realization of Drilling Authorization for Expenditure (AFE) (excel and pdf document).
   The example of well memo/postmortem report, form 19-I, recapitulation of daily drilling report, final time distribution, also budget and realization of drilling authorization for expenditure (AFE) can be found in Appendix 2. Example of Drilling Project Close-out Performance Reporting.

The adoption of such a thorough reporting structure ensures meticulous record-keeping and performance analysis. The well postmortem and form 19-I, for example, provide detailed breakdowns of drilling activities, costs, and

equipment used, allowing for a deep dive into operational efficiencies and financial accountability. Such documents also enable a transparent review of time distribution, operational summary, and a comprehensive comparison of planned versus actual well depth and costs.

By integrating these oil and gas industry practices, geothermal stands to benefit from enhanced project evaluations, facilitating the identification of cost-saving opportunities and efficiency improvements. Moreover, these reports can aid in minimizing non-productive time (NPT) through a detailed analysis of past projects, which can directly lead to a more economically robust and technically sound approach to future drilling endeavors.

The adoption of the drilling performance reporting format used in Indonesia's oil and gas industry signifies a strategic shift towards more disciplined, transparent, and efficient operations within the geothermal sector. It underscores a commitment to continuous improvement, fostering an environment where data-driven decision-making propels the industry forward. The rigorous analysis made possible by these reports will not only bolster the performance of individual projects but also contribute to the broader goal of sustainable and responsible energy development in Indonesia. Thus, this practice is not merely an administrative change but a cornerstone for the future of energy resilience and the optimization of geothermal resources in the country.

3.4 Strategies for Developing Indonesia's Geothermal Drilling Database

Based on the discussion above, several potential ways forward for developing Indonesia's geothermal drilling database can be drawn as follows:

1. **Develop a Standardized Drilling Cost Reporting Format.**
   EBTKE is recommended to establish a standardized reporting format regarding the geothermal drilling cost reporting. Developing standardized drilling cost structure can be done by adopt and modify the established cost structure in Indonesian oil and gas industry (BS 19 and BS 20) and previous drilling cost structure that already submitted by geothermal developers. It will enable a quick cost and performance analysis using common metrics such as: Days per 10k feet drilled (days/10k); USD per meter (US$/m), total NPT (days) and any related analytics that are usually used in geothermal drilling cost analysis.
2. Develop a Standardized Drilling Performance Reporting Format.
   EBTKE is recommended to establish a standardized reporting format for drilling performance benchmarks. Learning from oil and gas industry in Indonesia that already well-established, EBTKE can consider obligating performance reporting for supporting geothermal drilling database with document as follows:
   a. Lesson learns and best practice extraction from:
      - Time Distribution (Drilling Time vs. Depth vs. Cost),
      - Productive Time and Non-Productive (PT & NPT) Time Distribution and Breakdown,
      - Recapitulation of Daily Drilling Report
   b. Summary of Operation in shape of Postmortem Report and Form 19-I document that adjusted for geothermal drilling project.
   c. Additional well information such as well pressure & temperature (P & T), also well output (MW)
3. **Government Enforcement on Cost and Performance Submission**
   There is an alternative that EBTKE can revise or amend current Regulation to mandate/obligate geothermal developers to adhere to the drilling cost and performance reporting format established by EBTKE. It is aimed to ensure transparency and consistency in drilling cost and performance reporting.
4. **Socialization to Key Role of Drilling Team of Geothermal Developers**
   Socialization related to the drilling cost structure and reporting format that is already standardized to geothermal developer is important. Proper socialization will increase geothermal developers' awareness of the new policy. Several key roles that must be invited during the socialization are Drilling Manager, Drilling Engineer, Drilling Cost Control, Performance Engineer, and any other related role that manages drilling data reporting and analysis in geothermal developer.
5. **Annual analysis and public disclosure.**
   Perform deep analysis on the drilling data annually using independent consultants and release to public according to the current regulation.
6. **Annual Geothermal Drilling Best Practice Sharing Session**
   The annual geothermal drilling best practice sharing session plays a crucial role in facilitating knowledge exchange and collaboration between regulators, geothermal developers, and service companies. It serves as a vital platform for sharing experiences, addressing recent drilling experiences, and promoting

innovation and efficiency in drilling practices. Such collaboration is essential for enhancing operational safety, reducing risks, and optimizing drilling cost.

Moreover, these sessions contribute significantly to the sustainable development of the geothermal sector by fostering the adoption of environmentally responsible drilling practices. They aid in skill development, ensure compliance with regulatory standards, and support the industry's commitment to sustainable energy development, benefiting not only the companies involved but also the broader community and environment.

The impact of the proposed way forward to geothermal drilling industry can lead to the cost and drilling performance reports submitted by geothermal developers to EBTKE will have a uniform/ standardized format. A standardized drilling cost structure format and performance reporting format used and followed by developers for reporting to EBTKE might be led to easier database entry and enable apple-to-apple analysis for performance benchmarking of each drilling project.

The standardized drilling cost and performance reporting also can be useful for extracting the lesson learn and best practices to optimize drilling preparation and operation among geothermal developers in Indonesia.

3.5 Implementation Framework

The development of a comprehensive geothermal drilling database is a multifaceted endeavor requiring thorough planning and execution. The following steps outline a strategic approach to creating this vital resource, ensuring it meets the industry's needs and adheres to best practices in data management.

3.5.1 Technical Specifications and Data Collection Protocols

To initiate the project for developing a geothermal drilling data database in Indonesia, the first step is to create a repository where this data will be stored. This can be done as follows:

1. Database Architecture: Develop a robust database architecture that can handle large volumes of data, ensuring scalability and ease of access. Define the technical specifications based on industry standards and specific requirements of the Indonesian geothermal sector. Figure 9 presents a simplified flowchart illustrating how drilling data is integrated into the database.

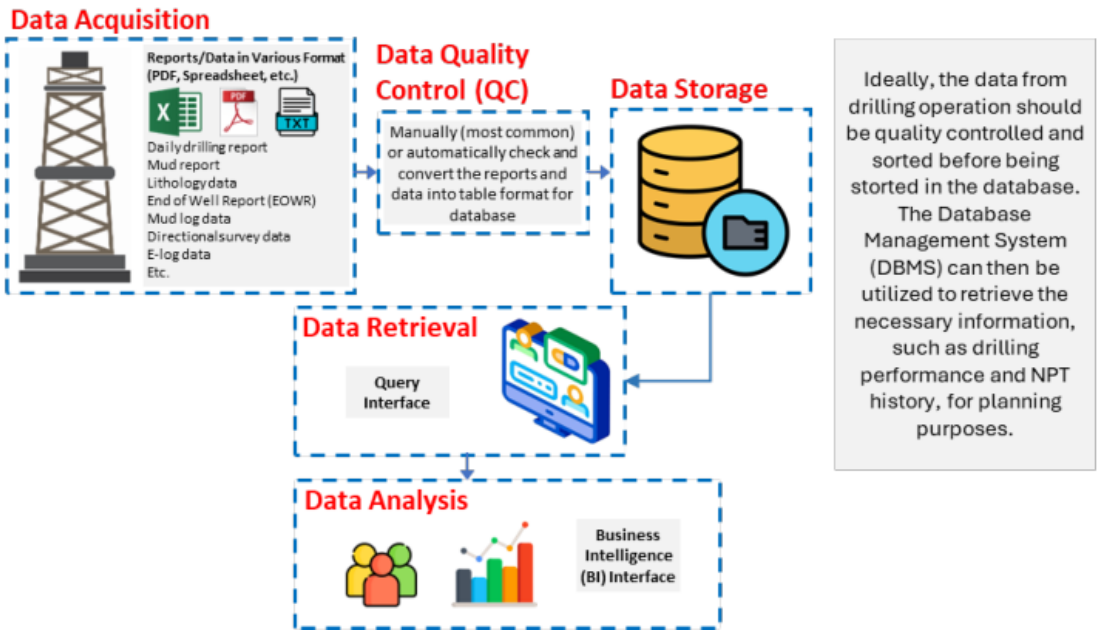

Figure 9: Illustration of Drilling Data Management (modified from Adityatama, 2021).

2. Data Standardization: Establish standardized formats and protocols for data submission to ensure consistency and comparability across different data sets.
    a. This includes defining key data fields, units of measurement, and classification schemes. The types of data that must be standardized and submitted to the Government of Indonesia can be agreed upon by forming a special Task Force comprised of representatives from geothermal developers, academia, drilling contractors, and drilling consultants.
    b. For the implementation of the pilot project database, where the actual cost is low, uncomplicated, and does not require extensive resources, we can utilize simple existing software such as Excel and Power BI (Figure 10).

c. Regarding data cleansing, it can be delegated to developers using a standardized data submission format provided by EBTKE. Consequently, developers are responsible for cleansing and formatting their drilling data before submission to EBTKE. Subsequently, an independent consultant can periodically (twice a year or annually) check the data accuracy through random sampling.

3. Data Collection and Submission: Implement secure and user-friendly mechanisms for data collection and submission. Encourage geothermal developers to contribute data by demonstrating the mutual benefits of shared insights and sector-wide improvements.

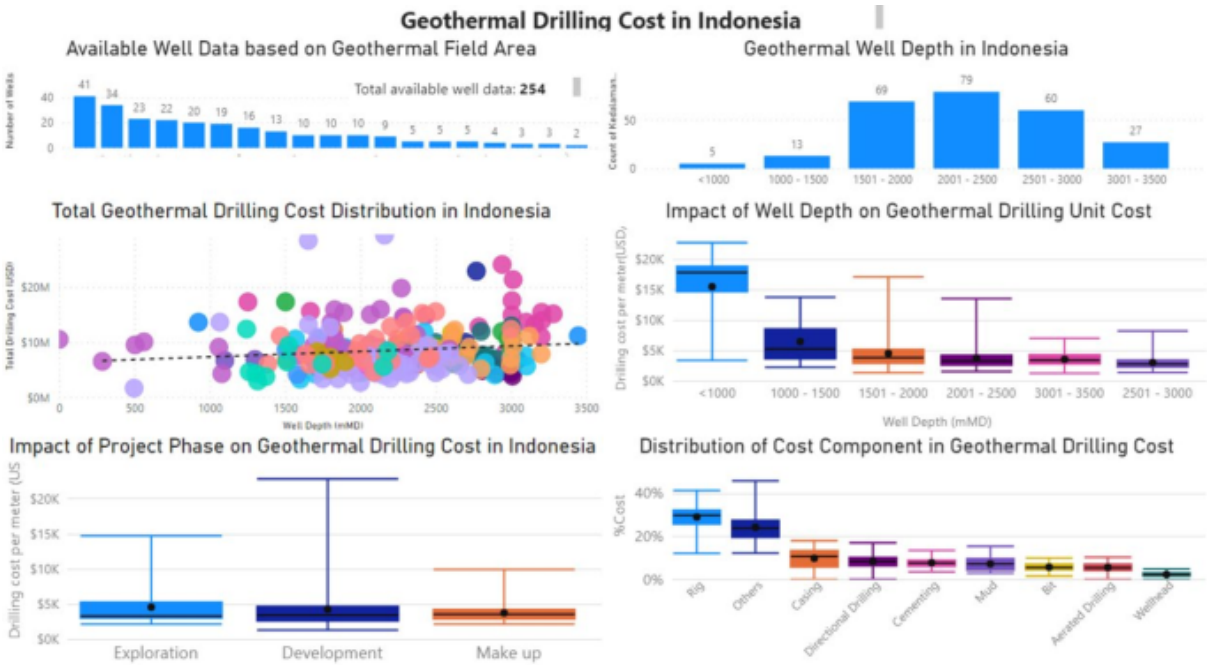

Figure 10: Example of utilization of simple existing software such as Excel and Power BI for geothermal drilling database pilot project.

3.5.2 Phased Integration Approach

Once the repository for data storage and retrieval is available, a small-scale pilot program should be conducted to test the system. This can then be gradually scaled up to involve more data incrementally:

1. Pilot Program: Initiate database development with a pilot program focusing on a specific region or subset of geothermal projects. This approach allows for the identification of potential issues and enables iterative improvements based on user feedback and initial outcomes.
2. Expansion and Scale-Up: Following the successful implementation of the pilot program, gradually expand the database to include additional regions and projects. This phased expansion facilitates continuous learning and adaptation, ensuring the database evolves to meet the sector's changing needs.

3.5.3 Government Leadership and Stakeholder Engagement

Given that all drilling data collected in the integrated database will be owned by the Government of Indonesia, the government will assume the role of coordinator for this initiative:

1. Government Coordination: Emphasize the crucial role of government bodies, particularly EBTKE, in leading and coordinating this initiative. Government leadership is essential for setting policy directions, mobilizing resources, and fostering collaboration across different stakeholders.
2. Stakeholder Engagement: Engage a broad spectrum of stakeholders, including geothermal developers, regulatory bodies, academic institutions, and industry associations, to ensure the database reflects diverse perspectives and needs. Active stakeholder engagement is key to building consensus, encouraging data sharing, and maximizing the database's utility and impact.
3. Resource Allocation: Advocate for the allocation of necessary resources, including funding, technical expertise, and administrative support, to facilitate the successful development and operation of the database.

3.5.4 Training and Capacity Building

1. Training Programs: Implement targeted training programs for all stakeholders involved in data submission and usage to ensure they are proficient in utilizing the database effectively. This includes training on how to input data, how to interpret the data outputs, and how to use the data for decision-making.
2. Capacity Building: Develop workshops and seminars that help build the necessary skills for database management, data analysis, and strategic use of data in geothermal development.

3.5.5 Legal and Regulatory Framework

1. Data Privacy and Security Protocols: Establish clear guidelines on data privacy, focusing on the protection of sensitive information and compliance with international data protection regulations.
2. Regulatory Support: Work with legislative bodies to create supportive policies that mandate data sharing among geothermal developers and define penalties for non-compliance, ensuring that data collection becomes a routine practice in the industry.

3.5.6 Continuous Improvement and Adaptation

1. Feedback Mechanism: Set up a structured feedback mechanism that allows users to report issues, suggest improvements, and adapt the database to better meet their needs over time.
2. Regular Updates and Maintenance: Ensure the database is regularly updated with new data, features, and security measures to keep it relevant and useful.

3.5.7 Marketing and Communication Strategy

1. Promotion Plan: Develop a comprehensive plan to promote the benefits and successes of the database to encourage wider adoption and utilization across the industry.
2. Stakeholder Communication: Maintain regular communication with all stakeholders through newsletters, updates, and forums to keep them informed about the database's progress, benefits, and ways to contribute.

4. DISCUSSION

Indonesia's geothermal energy development faces significant delays due to the absence of an integrated drilling data database, which severely impacts cost analysis, strategic planning, and operational efficiency. The lack of standardized data collection and the confidential nature of existing data restrict public access and detailed analysis. This situation delays collective learning among geothermal developers, especially new entrants, as they cannot benefit from the challenges and experiences of established developers in similar projects.

This lack of shared knowledge leads to inefficient planning and execution of drilling projects, inflating costs detrimentally for Indonesia. Unlike global practices where platforms like IHS Rushmore enable data sharing and foster innovation, the absence of a similar system in Indonesia stifles benchmarking and internal efficiencies. Establishing a unified database is essential to enhance transparency, enable effective cost management, and boost the competitiveness of Indonesia's geothermal industry.

This paper has provided actionable recommendations to establish standardized regulations for the collection and management of geothermal drilling data. Such standardization would increase data accessibility and transparency, aligning Indonesia with global data management practices like the IHS Rushmore platform, thereby enhancing project planning, reducing costs, and boosting competitiveness in the global geothermal energy market.

The proposed integrated data framework is designed to resolve data access challenges and harmonize data reporting, thus enabling robust cost analysis and sector-wide benchmarking.

By institutionalizing these measures within the geothermal sector, Indonesia can significantly enhance its geothermal drilling cost analysis and optimization, reinforcing its position as a leader in global geothermal energy development. This initiative calls for a united front from all sector stakeholders to champion data-driven improvements, leveraging Indonesia's geothermal potential to its fullest in a sustainable and economically viable manner.

Implementing this integrated data framework presents several challenges that need to be addressed. Firstly, establishing standardized data collection protocols across various stakeholders requires significant coordination and agreement, which can be time-consuming and complex. Secondly, ensuring data confidentiality while promoting transparency and data sharing poses a delicate balance that must be carefully managed to maintain trust among developers. Thirdly, the initial costs of setting up the database infrastructure and training personnel may be substantial, requiring strong financial and institutional support. Lastly, there may be resistance to change from stakeholders accustomed to existing practices, necessitating effective communication and advocacy to

demonstrate the long-term benefits of the new system. Overcoming these challenges will be crucial for the successful implementation and sustainability of the geothermal drilling database in Indonesia.

In conclusion, addressing the current gaps in data integration and standardization is crucial for Indonesia to fully realize its geothermal potential. A collaborative effort among government bodies, developers, academia, and industry professionals is necessary to implement a robust and transparent geothermal drilling database. This will not only streamline operations and reduce costs but also foster innovation and ensure Indonesia's competitive edge in the global geothermal market. By committing to these improvements, Indonesia can pave the way for a more efficient, cost-effective, and sustainable geothermal energy sector.

Keywords: sump pit, lighting, thermoelectric generator (TEGs), condensate, low enthalpy resources, steam field, waste heat, energy efficiency

ABSTRACT

Geothermal power plant uses steam to generates power, the steam was exploited from steam field around the power plant, and because of the long distance piping system, steam tends to lose it temperature gradually and undergo phase changes to water, this water will usually be collected automatically from automatic drain pot (ADP) and will be streamed directly into sump pit located in well pad area. Collected condensate still has low enthalpy, and usually this heat is wasted through the air, heat also wasted at flange through which is not covered by pipe isolation to cover the heat. Applying Thermoelectric generation technology provides a solid-state solution for the direct conversion of thermal energy into electricity. This approach stands in contrast to traditional methods that rely on mechanical work, offering a unique advantage with thermoelectric power converters (TEG) that are devoid of moving parts. This results in a compact, silent, reliable, and eco-friendly power solution. This idea is to harness the potential of thermoelectric generators to tap into the low-enthalpy thermal energy present in each sump pit within a steam field. This power generation system employs TEG modules, fabricated using cost-effective methods, to achieve superior efficiency in converting thermal energy to electricity. The electricity generated from this system is intended for lighting in local well pad, and public street. Our findings underscore the promise of thermoelectric generation technology in enhancing energy efficiency and sustainability.

1. INTRODUCTION

In the realm of renewable energy, geothermal power plants have long been recognized for their potential to generate electricity using the Earth's natural heat. However, the efficiency of these systems is often compromised by the loss of thermal energy during the transportation of steam from the steam field to the power plant. This paper aims to address this issue by introducing an innovative approach that harnesses the wasted thermal energy to generate electricity. The focus of our study is the application of Thermoelectric Generation (TEG) technology, a solid-state solution that directly converts thermal energy into electricity. Unlike traditional methods that rely on mechanical work, TEG offer a unique advantage as they are devoid of moving parts, resulting in a compact, silent, reliable, and eco-friendly power solution. Our research explores the potential of TEG to tap into the low-enthalpy thermal energy present in each sump pit within a steam field, and uncovered flange along the existing main steam piping. We employ TEG modules, fabricated using cost-effective methods, to achieve superior efficiency in converting thermal energy to electricity. The electricity generated from this system is intended for lighting in local well pad and public streets, thereby enhancing energy efficiency and sustainability. This paper presents our findings and underscores the promise of thermoelectric generation technology in enhancing energy efficiency and sustainability in geothermal power plants. We believe that our research will contribute significantly to the ongoing efforts to optimize the use of renewable energy sources and pave the way for more sustainable and efficient power generation systems.

2. MATERIALS AND METHOD

This experiment uses a simple method to demonstrate the potential for generating electricity from TEG. The test is carried out directly by placing the TEG module on the waste heat source that has been collected in the sump pit to simulate the generation potential, using three TEG panels connected in series. The waste heat source is hot water condensate collected in the sump pit from the steam line, the hot side of the module will be installed directly around the condensate pipe, and for cooling will use cold air directly from the surrounding environment, which will pass through the cold side of the module through the heat sink. Thermal paste is used to ensure that the hot and cold temperatures in the module are evenly distributed. The TEG panel will convert ΔT from both sides of the module into DC voltage that can be used to charge the battery, and also to light the lights through the inverter. It is hoped that it can reduce electricity infrastructure bills in the future. This TEG has three main parts, including: 1. TEG Module, 2. Heat Sink, 3. Spacer.

2.1 TEG Module

The module used in this experiment is made of ceramic/Bismuth Telluride (Bi2Te3) as shown in Figure 1. This module was chosen because it is easily available on the market and its price is quite affordable. The specifications of this module can be seen in Table 1. These modules will be arranged in series, with a distance between modules of 20 mm and a distance between the module and the heat source of 0.2 mm which will be limited by using an aluminum spacer.

Table 1: TEG Module Spesification.

Specification	Value
Material	Ceramic / Bismuth Telluride (Bi_2Te_3)
Model Number	SP1848-27145
Maximum Temperature (°C)	150
Open Circuit Voltage (v)	4.8
Color (mm)	White
Width (mm)	40
Length (mm)	40
Height (mm)	4
Weight (gm)	30

Figure 1: TEG Module.

Figure 2: Heat Sink.

2.2 Heat sink

The material of the heat sink is aluminum which possessed light weight and good thermal conductivity. This heat sink was cut according to the TEG module size, to properly mount at the surface of module cold side. Thermal paste was applied between the heat sink and module cold side to insure cooling distribution spread evenly.

2.3 Spacer

The spacer is an aluminum component which is used to maintain the gap between TEG module hot side and the heat source, so the TEG does not directly stick to the heat source. It also will help to distribute the heat spread evenly on the hot side by applying thermal paste.

This TEG panel has a simple construction and has aluminum material that can transfer heat easily to the heat sink on the cold side, and the spacer on the hot side. this will simplify maintenance and the relocation process if necessary.

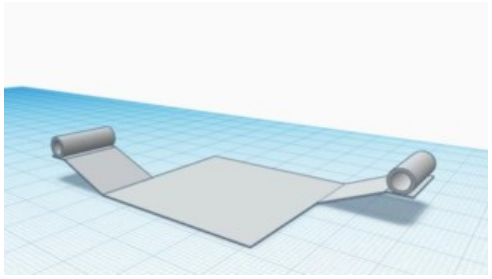

Figure 3: Spacer.

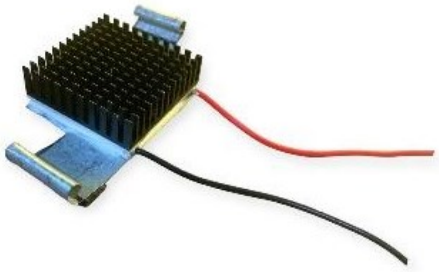

Figure 4: TEG Panel Assembly.

2.4 Proposed 3 TEG Panel

As in figure 5. The TEG panels will be connected in series. The heat source comes from the zero discharge condensate pipe, while for cooling it will use passive cooling from the surrounding air that will pass through the heat sink. On the hot and cold sides of the module will use thermal paste to help even out the temperature distribution.

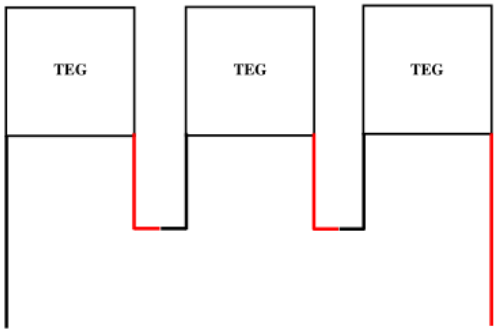

Figure 5: Schematic diagram of 3 TEG panel.

2.5 TEG System Efficiency

The Seebeck effect uses temperature differences to generate electricity in thermoelectric devices built from the junction of two materials. Temperature differences can be converted into other types of energy through several technologies (Esen et al., 2012). Any device that converts temperature differences into energy has a Carnot efficiency as a fundamental limit. Using the Carnot efficiency which can be calculated using equation (1) below (G. Kumar et al., 2017). With Th and Tc, respectively, representing the hot and cold temperatures that form the temperature difference.

$$\eta c = \frac{\mathrm{Th} - \mathrm{Tc}}{\mathrm{Th}} \tag{1}$$

3. RESULTS AND DISCUSSION

3.1 Effect of Passive Cooling and Heating Method on The Temperature Difference of 3 TEG Panel

Heating and cooling of the appropriate thermoelectric material will increase the efficiency, the method is passive or active (B. Pfeiffelmann et al., 2021). In this experiment, passive cooling is used which utilizes the surrounding air directly, but the results of this passive cooling have large thermal resistance and have a negative impact on the power output. From the three TEG panels that were tested experimentally starting at 17:00 and lasting for 2 hours, it can be seen that at the beginning of the experiment (Tc) was at 16^{o}C, which then increased due to the influence

of (Th), after some time and reached a stable condition at 56 °C. The hot side (Th) and cold side (Tc) temperatures are in Figure 6.

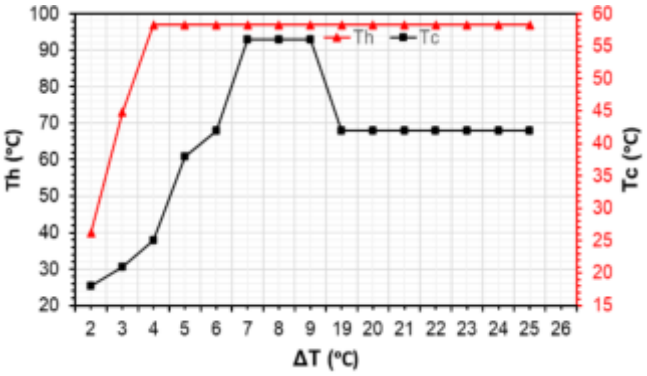

Figure 6: ΔT, Th, Tc of a 3 TEG panel.

3.2 Performance of 3 TEG Panel

The voltage generated at the terminal with ΔT across the TEG module is shown in Figure 7. From this figure it can be seen, at the beginning of the experiment, the open circuit (Voc) is 0 v, and rises to 9.81 v, then stabilizes at 5.73 v. This shows that the output voltage is proportional to ΔT.

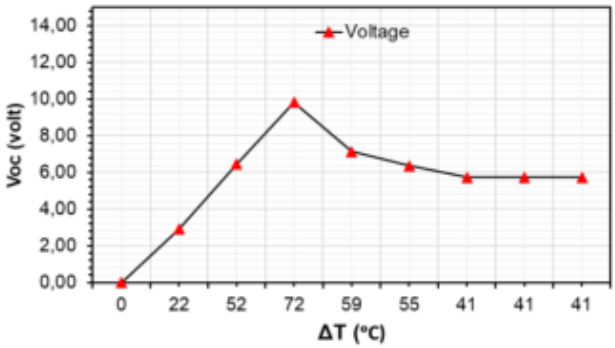

Figure 7: Open circuit voltage of 3 TEG panel.

3.3 Carnot Efficiency of TEG Panel

TEG shows the Carnot efficiency at various values of ΔT determined using equation (1) the results of which can be seen in figure 9. The Carnot efficiency (ηc) of the TEG module depends on the temperature of the hot and cold sides of the module which has an average of 1.29%.

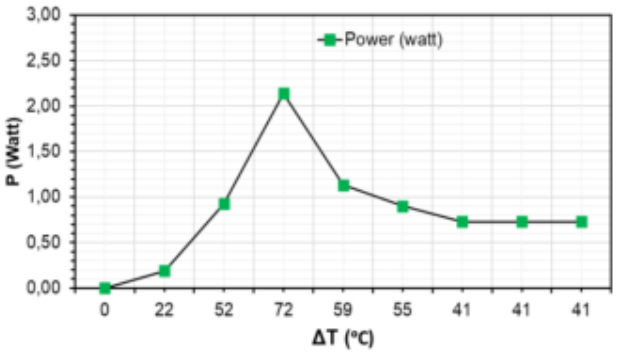

Figure 8: Power of 3 TEG panel vs ΔT.

3.4 System Implementation Cost Estimation and Economic Analysis

Economic analysis and cost assessment for system installation are two important considerations of the project (Awan et al., 2022). This section estimates the cost of a 3 TEG panel from its key component, as shown in table 2.

This experimental TEG panel was built with cheap material because it only aims to show potential of opportunities for power generation from low enthalpy resource in steam field that could be used as an option for future electrical infrastructure.

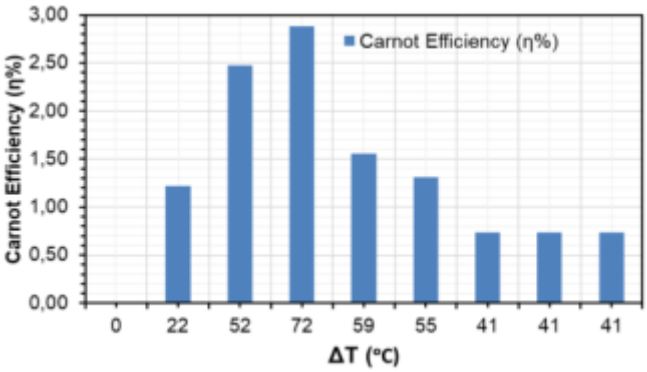

Figure 9: Carnot Efficiency of 3 TEG panel.

Table 2: Component costs of TEG Panel.

Component	Cost (idr)
TEG Module	35.000
Heat Sink	12.000
Spacer	5000

4. CONCLUSION AND FUTURE WORK

From this experiment, it can be concluded that the TEG panel is able to produce power and voltage that can be utilized later for lighting purposes in the local area and can also be used as an option to cut the cost of pulling cables for electricity needs in the local area. With low implementation costs, this approach can be recommended for a cheap and efficient electrical system. In the future, to generates more power, applying active cooling and heating method to increase and control ΔT, and use larger number of TEG modules is recommended. Furthermore, applying ten check algorithms might help to improve the performance of TEG panel (Awa Afzal et al., 2018).

Keywords: Empowered Community, Renewable Energy, Geothermal Development, Society

ABSTRACT

This research aims to investigate the influence of Geothermal Coffee Process (GCP) as a community development initiative by PT. Pertamina Geothermal Energy Tbk. Area Geothermal Kamojang on the education and awareness enhancement of the public regarding renewable energy, specifically in the context of geothermal business and its benefits to society. GCP serves as a tangible manifestation of the company's Corporate Social Responsibility (CSR) program, wherein direct utilization of geothermal energy as a source of heat energy in processing the coffee products produced, especially the process of drying coffee beans. This presents a potential new avenue for expanding public education on geothermal energy. Therefore, this research seeks to examine whether the direct utilization of geothermal heat by the Geothermal Coffee Process (GCP) community group can contribute to the development of education on renewable energy or if its focus remains limited as a form of the company's CSR program. The study is conducted around Kamojang, Laksana Village, Bandung Regency, utilizing a qualitative methodology. Data collection involves observation, interviews, and documentation to gather both qualitative and measurable quantitative data. The research findings indicate that GCP has a significant impact on the development of education regarding renewable energy and its utilization by the community through the activities undertaken by the empowered community.

1. INTRODUCTION

PT Pertamina Geothermal Energy Tbk AG Kamojang Area is situated between two regencies, with the majority of the area located in Bandung Regency and the remainder in Garut Regency. The history of geothermal energy exploration in Indonesia began at Kamojang, Bandung. Exploration of geothermal energy at Kamojang commenced in 1918 under Dutch colonial government. In 1974, the government assigned PT Pertamina the task of surveying geothermal sources and conducting exploration and exploitation for electricity generation. In 1983, the Kamojang Geothermal Power Plant Unit I officially commenced operations, capable of generating 30 MegaWatts (MW) of electricity. PGE AG Kamojang Area has continuously increased its electricity production capacity utilizing geothermal energy. Currently, PGE AG Kamojang produces 235 MW of electricity.

Development Stages:
a. Drilling 1 : 1926
b. COD PLTP Unit-1 : 1983
c. COD PLTP Unit-2 & 3 : 1987
d. COD PLTP Unit-4 : 2008
e. COD PLTP Unit-5 : 2015

PGE AG Kamojang produces electricity to supply Java, Madura, and Bali. The average annual electricity production reaches 1,752 GWh. PGE AG Kamojang has successfully reduced emissions by 1.23 million tCO_2e per year, equivalent to 4.057 million Barrels of Oil Equivalent (BOE). The establishment of PGE AG Kamojang has enabled annual foreign exchange savings of 264,000,000 US dollars. Assuming a household electricity requirement of 450 V, PGE AG Kamojang can supply electricity to approximately 522,000 homes in Java, Madura, and Bali.

PT Pertamina Geothermal Energy Tbk, as a publicly listed company, adheres to the Environment, Social, and Governance (ESG) Risk Rating, achieving a top-tier ranking of 1 in the categories of renewable energy companies and manufacturing companies, and ranking within the top 10 overall. This ESG assessment was conducted by Sustainalytics, receiving a score of 8.4, categorized as negligible risk, and a score of 2.0 for Good ESG Performance from Sustainable Fitch. In terms of achievements, PGE AG Kamojang stands as the sole power generation company to receive the PROPER Gold Award 13 times consecutively since 2011. In addition to the PROPER Gold awards, PGE AG Kamojang has also garnered 146 awards across various levels, spanning local, national, and international recognition.

As part of its corporate social and environmental responsibility to the community, PGE AG Kamojang has contributed to various community development programs based on the company's 5 pillars of CSR: empowerment, education, environment, health, social, and infrastructure. In an effort to create new innovations in the field of CSR, PGE AG Kamojang has developed a program using direct-use geothermal known as the Geothermal Coffee Process (GCP). This program aims to use residual steam from steam traps for drying coffee through a Geothermal Dryhouse. Through this innovation, there are significant impacts for both the company and the community.

2. METHODOLOGY

In conceptualizing how the discourse on geothermal energy as renewable energy is developed within the community through the Geothermal Coffee Process (GCP), this research is accompanied by a capacity building mechanism for a deeper examination.

The empowered community of PGE AG Kamojang, namely the Geothermal Coffee Process (GCP), serves as a medium in developing the discourse on geothermal energy as renewable energy, adding a new dimension to this discourse. Through the capacity building mechanism, a further investigation will be conducted on how the Geothermal Coffee Process (GCP), as a empowered community of PGE AG Kamojang, actively plays a role in expanding the discourse on geothermal energy as renewable energy to the community. According to Chelminski (2018), the capacity building mechanism is described as the provision of resources for developing human capacity, either through training and education. In this research, the capacity building mechanism may take the form of training coffee farmers, benchmarking by external parties in exploring direct-use geothermal in the CSR Program through the Geothermal Coffee Process (GCP), coffee exhibitions, and other informal activities of the GCP group.

3. DISCUSSIONS

Innovation through the direct-use of geothermal in the field of CSR also creates a new approach to developing community knowledge about geothermal discourse. Through the Geothermal Coffee Process (GCP), educational tools for the community become more extensive by showcasing the benefits of geothermal energy beyond its use for electricity generation. This research is focused on examining the impact of the Geothermal Coffee Process (GCP) as an empowered community initiative by PT. Pertamina Geothermal Energy Tbk. AG Kamojang on the development of renewable energy discourse among the society.

3.1 New Innovation through Geothermal Coffee Process (GCP)

Kamojang is located in a mountainous region that is administratively part of Laksana Village, Ibun District, Bandung Regency. The hilly terrain of Kamojang results in the majority of its residents being farmers, including coffee farmers, vegetable farmers, and others. In the farming profession, unpredictable weather is one of the issues that can hinder agricultural processes, especially coffee farming, which requires a drying period of up to 45 days. Unstable weather conditions can obstruct the drying process and lead to ineffective coffee production.

The unstable weather conditions that hinder coffee farming, particularly in the areas surrounding the company's operations, have prompted PGE AG Kamojang to create a new innovation that addresses the problems faced by coffee farmers. After extensive research and trials, a new innovation was developed to tackle this issue: the Geothermal Dry House. This device is a coffee drying house that utilizes direct geothermal energy in its drying process by using residual steam from the blowdown line, which is channeled through pipes to heat the coffee drying house. This innovation is utilized by the company's empowered community, who are part of the Geothermal Coffee Process (GCP), consisting of coffee farmers from the areas around the company.

In community empowerment activities around the company, the empowered community acts as a subject collaborating with the company to achieve common goals. Community empowerment itself aims to provide independence and positive change amidst existing problems. Broadly, these activities are divided into four aspects that promote the creation of an independent and prosperous empowered community.

These four aspects are infrastructure, charity, capacity building, and community assistance. The Geothermal Coffee Process has implemented and developed these four aspects. The GCP Group consists of three coffee groups from Ibun District, namely Akkar Kopi and Ecovill Kopi, and one group from Samarang District, namely Penyoe Kakopi. Each member of the GCP collaborates with the company to achieve common goals in developing coffee products processed through the Geothermal Dry House, branded as Canaya Geothermal Coffee.

3.1.1 Geothermal Dryhouse Innovative Infrastructure

The innovation of the Geothermal Dryhouse, as a form of direct use of geothermal energy, can have a direct impact on the community. This direct utilization not only assists coffee farmers and processors in addressing issues in coffee processing but also provides positive economic, social, and environmental value. The technological innovation in the form of the dry house encourages farmers to learn how to use the equipment and

disseminate information about direct use geothermal to the broader community. Supporting infrastructure for production benefits farmers as the geothermal dry house brings values of efficiency and effectiveness in drying coffee cherries. This infrastructural innovation accelerates actors in expanding the utilization of geothermal energy more broadly. The slow pace of innovation, adoption, and development of clean technology innovations in developing countries is largely attributed to market and institutional failures such as lack of information, transaction costs, weak financing institutions, and poor technological adaptability to the developing country's absorptive capacity or technological sophistication (Acemoglu et al., 2012; Dechezleprêtre et al., 2012; Stoneman and Diederen, 1994 in Chelminski, 2018).

The advantage of the Geothermal Dryhouse is that it can dry coffee 75% faster than conventional sun-drying methods. Previously, drying coffee would take 30-45 days, but now it takes only 3-10 days around Kamojang, where the weather is often foggy and rainy. Drying in the dry house can occur 24 hours a day with fluctuating temperatures between 26 to 50 degrees Celsius. The temperature dynamics, which are made as natural as conventional drying, can maintain the distinctive characteristics and flavors of Kamojang Arabica coffee.

The market potential for geothermal dry house technology within the next 5 years in the coffee industry appears promising. The efficiency, quality assurance, and extended drying capabilities through expansion of the geothermal dry house can attract more coffee farmers and buyers, leading to potential growth and market expansion:

a. Increased Efficiency: The geothermal dry house can accelerate drying time significantly, up to 75% faster than conventional methods. This increased efficiency can lead to higher productivity and throughput in coffee drying processes.
b. Extended Drying Season: The ability to dry coffee beans regardless of the season can provide a competitive advantage to coffee farmers, allowing them to operate year-round and be less affected by seasonal variations. This extended drying season could attract more farmers to adopt this technology.
c. Stable Drying Conditions: The stability of drying temperature and humidity in geothermal dry houses can help maintain the quality of coffee beans, ensuring that the flavor is not compromised. This quality assurance can be a crucial selling point in the market.
d. Contamination Reduction: By reducing the risk of contamination from dust, dirt, and insects, the geothermal dry house method ensures higher-quality coffee beans. This assurance of quality can be a key factor in attracting buyers who prioritize cleanliness and quality standards.
e. Consumer Preference: The positive testimonies from local coffee farmers regarding the taste and absence of smell issues in the dried coffee could lead to increased consumer trust and preference for dried coffee using geothermal technology.

With its array of advantages, geothermal dry house technology presents promising potential for significant market growth and expansion in the coffee industry over the next five years. By enhancing efficiency, extending drying seasons, ensuring stable drying conditions, reducing contamination risks, and garnering increased consumer preference, this technology opens new opportunities for coffee farmers and stakeholders across the coffee supply chain to optimize quality and productivity, while expanding their market share.

In addition, the limitation of this tool lies in its restricted area of use. Direct use can only be accessed in the area around the company's operations, meaning that only the community partners can directly utilize the dry house. Communities from outside the area can also benefit from the dry house, but in a limited system. One way is by drying coffee cherries in the dry house under a makloon system, which is also managed by the GCP Group. Nevertheless, the broader use of the dry house directly promotes the development of geothermal energy to be more widely recognized. The replication of the dry house and its increasing capacity usage requires monitoring and supervision by the company's maintenance, operation, and HSE teams. To ensure that the infrastructure is safe and functions properly, periodic technical descriptive reviews of the Geothermal Dryhouse are necessary. Below is a technical overview of the design and the steam trap system that channels steam inside the dry house.

The existing Geothermal Dryhouse has a width of 6 m, length of 8 m, and height of 4.5 m, as shown in Figure 1. The heating pipe utilizes the blowdown from the main pipeline as the heat source so that the geothermal steam flows from the blowdown towards the dryhouse to transfer its heat to the dry house air. The total length of the existing heating pipe is 43.5 m.

The actual documentations of the existing geothermal dryhouse and heating pipe connection to the main pipeline's blowdown are shown in Figure 2. The dryhouse has three coffee tables with a single U-loop heating pipe under each table. The heating pipe is made of carbon steel with the specification code of SMLS Pipe CS API 5L Gr B 1" SCH 40.

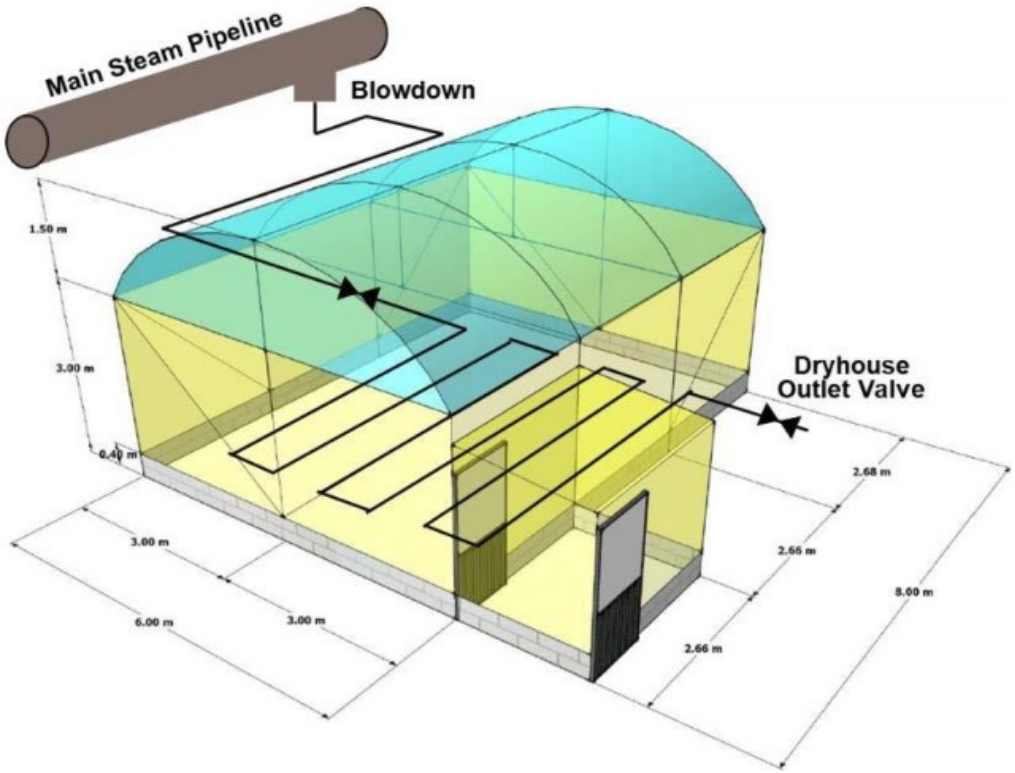

Figure 1: Existing Geothermal Dryhouse Dimensions and Heating Pipe Schematic.

Figure 2: Existing geothermal dryhouse dimensions and heating pipe connection to the blowdown.

In order to maintain the dry house temperature at a desired value, the heating load must be equal to the rate of heat loss and the rate of trapped radiation. The geothermal steam flows inside the heating pipe and transfers its heat to the dry house air. This involves convection heat transfer on the inner and outer pipe walls, conduction heat transfer at the pipe wall, and radiation heat transfer on the outer pipe walls. The thermal circuit of the heat transfer process.

The geothermal steam flowing inside the heating pipe is at saturated vapor phase. Therefore, film condensation occurs as the steam transfers heat to the dry house air. The heating pipe is operated by opening the blowdown valve hence the geothermal steam from the main pipeline could flow inside the heating pipe towards the dry house. Meanwhile, the outlet valve at the end of the heating pipe remains closed. During the pipe operation, the dry house temperature is measured using a thermo hygrometer. Therefore, the dry house air temperature during the heating pipe operation could be evaluated. After a minimum 24 hours of operation, the blowdown valve is closed again to shut down the heating pipe.

Geothermal Dryhouse has the advantages of being weather-independent, available heat around the clock, and naturally-controlled temperature and humidity. Based on technical evaluation the results indicated that the heating pipe was able to increase the dry house temperature. However, the condensate builds up inside the heating pipe reduces the dry house temperature minutes after the heating pipe operation. Therefore, it is responded by installing two stream traps, each installed at the inlet and outlet of the drying house to reduce condensate in the steam

entering the drying house and remove the condensate formed while the steam is in the drying house. The actual operation hours for geothermal dry house entail a continuous cycle of work, with operations spanning 24 hours each day. This setup results in a substantial cumulative working time of 5,760 hours annually.

Maintenance Scheme of Geothermal Dryhouse conducts proactive and preventive maintenance with regular schedules to avoid production failures. These plans are maintained based on manual machine operation data, predictive maintenance principles, and machine degradation level analysis. In line with the concept of sustainable power plant operations, socio-ecological safety is ensured through social inclusion practices in the Geothermal Coffee Process program, and monitored through annual Social License Index (for social safety) and annual geophysical surveys (for steam resource sustainability).

The heightened interest of the community in the Geothermal Dryhouse has boosted the productivity levels of the Geothermal Coffee Process. To meet this rising demand, replication of the Geothermal Dryhouse is being undertaken to further enhance the productivity of the Geothermal Coffee Process.

Figure 2: Geothermal Dryhouse Replication.

3.2 Geothermal Coffee Process (GCP) impacts on the Discourse Development of Renewable Energy Among the Society

As an empowered community of PGE AG Kamojang's CSR Program, the Geothermal Coffee Process (GCP) serves as an example of how geothermal energy can be utilized not only for electricity generation but also for direct community empowerment. Through the capacity building mechanism, the impact of the Geothermal Coffee Process (GCP) on the development of the discourse on geothermal energy as a renewable energy source is explained as follows.

3.2.1 Capacity Building Through Geothermal Coffee Process (GCP) and PGE AG Kamojang

In an effort to develop geothermal energy through educational initiatives, the first approach undertaken by the GCP Group involves activities such as training, workshops, and capacity building. The initial activity is a workshop for the GCP Group, aimed at enhancing the capacity of coffee farmers as an empowered community benefiting from the company's CSR program through direct use of geothermal energy.

The next step is the coffee training provided by the GCP Group to raise awareness among the community, particularly coffee farmers, about the innovative Geothermal Dryhouse. This innovation has a positive impact on coffee farming by introducing a more efficient coffee processing method compared to conventional methods. Through this training, approximately 42 coffee farmers gain knowledge about utilizing geothermal energy for coffee farming. They participate in practical sessions on harvesting, seedling, and fertilizing coffee plants at Mr. Nono's farm. Some farmers bring tools such as hoes, soil perforation pipes, commonly used fertilizers, and special cutters or scissors for coffee plant cuttings. The farmers actively listen and ask questions to the instructor. Among the questions are how to increase coffee productivity or yield, the spacing for planting coffee seedlings, the criteria

for sustainable coffee seedlings that do not harm future harvest growth, and alternative fertilizers and their appropriate quantities to enhance the growth rate of coffee plants.

Figure 3: Coffee Training with Coffee Farmers.

Figure 4: Field Coffee Training with Coffee Farmers.

Farmers have also expressed several challenges in maintaining the supply of coffee cherries to downstream actors. One of the main challenges is the unpredictable annual fluctuation in coffee cherry prices, which is usually influenced by the quality of the coffee harvest each year, including the quantity of coffee produced in each harvest season.

The obstacles faced by coffee farmers also stem from the inadequacies in the infrastructure used to cultivate and develop coffee plantations. The equipment used by farmers significantly impacts their ability to care for their crops, highlighting the need for adequate materials and methods to support farmers in increasing the productivity of their coffee harvests. Collaboration with various stakeholders and benchmarking in different locations were suggested by several coffee enthusiasts participating in the training.

Increased coffee productivity will lead to higher harvest quantities each season. Therefore, several factors directly influence or encourage farmers to be interested in utilizing the Geothermal Dry House's direct-use services. The more farmers educated on improving coffee farm management and coffee cherry processing, the higher the coffee productivity, impacting farmers' ability to meet market demand. Additionally, farmers and the broader community will become more aware of geothermal energy as a clean and environmentally friendly energy source that can support existing local business processes.

3.2.2 External Visitors to Geothermal Coffee Process (GCP)

Figure 5: External Benchmarking.

PGE AG Kamojang frequently receives visits from schools, universities, companies, and various other groups. The purpose of these visits varies depending on the needs of the guests, whether for education, benchmarking, or other reasons. Each visit includes materials related to the CSR Program of PGE AG Kamojang, which encompasses the Geothermal Coffee Process (GCP). Additionally, there are visits to the Geothermal Dryhouse to observe the coffee processing conducted by the Geothermal Coffee Process (GCP). This serves as a new learning medium for visitors to study the direct use of geothermal energy for coffee drying. The total number of visitors over the past two years has reached approximately 10,000 people from diverse backgrounds.

3.2.3 Geothermal Coffee Process through Exhibitions

The Geothermal Coffee Process (GCP) has had the opportunity to participate in various exhibitions at regional, national, and international levels. For example, West Java Festival 2023, IIGCE 2023, IIGW 2023, Coaching Clinic PROPER Exhibition 2023, Forum CSR Jawa Barat 2024, Dekranas 2024,Global Geothermal Impact Summit 2024, Clean Energy Ministerial Senior's Official Meeting & Gathering 2024 and other exhibitions. These opportunities have been maximized to serve as a medium for expanding the discourse on the direct utilization of geothermal energy. Additionally, these occasions have been used to showcase the excellence of PGE AG Kamojang in the direct utilization of geothermal energy through its CSR Program, featuring the Geothermal Dryhouse and its product, Canaya Geothermal Coffee, which has become a hallmark of PGE AG Kamojang and the Geothermal Coffee Process group.

Figure 6: Geothermal Coffee Process on Exhibitions.

Exhibitions provide an opportunity for the Geothermal Coffee Process to expand its network across various groups, including the general public, coffee enthusiasts, coffee entrepreneurs, and others. Thus, this medium not only serves to broaden the discourse on geothermal energy but also aims to increase public interest in directly experiencing coffee produced using geothermal energy.

3.2.4 Geothermal Coffee Process Other Activities

Capacity building agendas and bootcamps are planned and partially realized to recruit outstanding talents that contribute to the sustainability of the Geothermal Coffee Group. At least 1,540 customers enjoy the GCP coffee products. Furthermore, the group strives to expand its business and market through both B2C and B2B models. Through The Canaya Geothermal Coffee, local community awareness of coffee cultivation potential increases, and with the presence of The Canaya Geothermal Coffee, it also supports the following beneficiaries: 6 main managers of The Canaya Geothermal Coffee, 15 Coffee Farmers, 4 Baristas, 2 Coffee Sorters, 1.537 coffee enthusiasts, and business partnerships with 35 B2B and B2C partners. In general, the Community Satisfaction Index (CSI) for the overall program of PT. Pertamina Geothermal Energy Tbk. Area Kamojang including The Canaya Geothermal Coffee scored 82.7, which falls under the A category for service quality, which is classified as very satisfied.

Figure 7: Drying Process in Geothermal Dryhouse.

Above is an activity of the coffee drying process inside the Geothermal Dryhouse. Several farmers are seen turning over coffee beans spread on tables, with steam flowing underneath through installed pipes. An 8 x 6-meter dry house can dry at least 4 tons of coffee beans per month. Meanwhile, the second dry house, measuring 16 x 4 meters, has a maximum capacity five times greater than the first dry house. This demonstrates that direct use of geothermal energy can significantly enhance productivity, effectiveness, and efficiency in achieving dried coffee bean quantities. Therefore, opportunities for coffee exports are wide open with broader stakeholder collaboration.

4. CONCLUSION

The community empowered through the Geothermal Coffee Process is a pioneer in the development of geothermal energy at local, national, and international levels. The compelling testimonials from this empowered society, experiencing direct benefits from geothermal direct use, provide broad access to narratives about geothermal energy for the wider community. The activities of the Geothermal Coffee Process (GCP), supported by corporate collaboration in infrastructure, capacity building, and facilitation of activities with external stakeholders, not only yield economic, social, and environmental benefits but also position the Geothermal Dryouse as an innovative tool in geothermal direct use that fosters significant opportunities in education and the advancement of renewable energy use in the future. As more people become educated about the positive benefits of geothermal direct use, there is an increasing likelihood that future geothermal development will be recognized and chosen by communities at local, national, and international levels.

Harnessing Low Enthalpy Energy: Innovatave Solutions for Sustainable Development

Fariz Alfarizi, Haris Mubarok, and Muhammad Farras Zahran Al-baihaqi

parisalfa09@gmail.com, harismubarok05@gmail.com, farrasbaihaqi7@gmail.com

Keywords: Low Enthalpy Geothermal, ORC, Kalina Cycle System, Renewable Energy

ABSTRACT

Indonesia has great potential in the development of geothermal energy, especially widespread low enthalpy geothermal resources. However, its utilization is still not optimal due to the limitations of existing technology. This paper introduces the innovation of merging two geothermal cycles, namely the merger of two main cycles in geothermal power plants, the Organic Rankine Cycle (ORC) and the Kalina Cycle System (KCS-34), which are designed to improve efficiency and flexibility in the utilization of low-temperature geothermal sources. Analysis of the merging system shows that this innovation is able to maximize the use of waste heat, resulting in higher energy output than conventional systems.

The simulation results show that this system has the potential to produce about 5,972 kW of power, with higher thermal efficiency than the stand-alone ORC and Kalina KCS-34. From an economic perspective, the system has a competitive Return on Investment (ROI), with an estimated payback period of around 8-10 years. In addition, this innovation has also succeeded in significantly reducing carbon emissions, making it a more environmentally friendly energy solution.

The potential application of this technology is not only limited to power plants, but also in various other sectors such as the processing industry, agriculture, fisheries, tourism, and construction. The paper concludes that with adequate regulatory and infrastructure support, this innovation can be the key to the sustainable development of renewable energy in Indonesia.

1. INTRODUCTION

Indonesia has tremendous geothermal energy potential because it is located along the Pacific Ring of Fire, which is a region with high volcanic and tectonic activity. According to data from the Geological Agency of the Ministry of Energy and Mineral Resources (EMR), the total potential of geothermal energy in Indonesia is estimated to reach 29,215 Megawatts (MW). This makes Indonesia one of the countries with the largest geothermal energy reserves in the world, which is even estimated to account for around 40% of the global geothermal potential. This figure is often referred to in various international reports, including those compiled by the World Bank.

In the context of the global energy transition to reduce dependence on fossil fuels, Indonesia has set ambitious targets to increase the contribution of renewable energy in the national energy mix. The government targets that by 2025, renewable energy will account for 23% of the total energy mix, and increase to 31% by 2050. Meanwhile, the use of petroleum is projected to be significantly reduced. However, the utilization of the great potential of geothermal energy in Indonesia is still far from optimal.

The Kalina cycle is a geothermal power generation system developed by Dr. Alexandre Kalina. The system is specifically designed to utilize low-temperature geothermal sources, which conventional power generation systems cannot use. One of the main advantages of the Kalina Cycle is the use of an ammonia-water mixture as a working fluid. This mixture has unique thermal properties that allow for higher energy efficiency than other similar systems.

Kalina Cycle System 34 (KCS-34) is a more advanced version of the traditional Kalina Cycle. This design aims to improve efficiency in utilizing residual heat from energy sources with low temperatures. The KCS-34 can operate at lower temperatures than traditional Rankine cycles, with operating temperatures typically ranging from 100°C to 180°C. By using an ammonia-water mixture, KCS-34 can regulate the mass fraction to maximize thermal efficiency, allowing this system to work more effectively in a variety of operating conditions. The use of KCS-34 in the geothermal context in Indonesia is very relevant, considering the large number of geothermal sources with low to medium temperatures spread throughout the country.

On the other hand, the Organic Rankine Cycle (ORC) is a thermodynamic cycle similar to the conventional Rankine Cycle , but it uses an organic working fluid with a low boiling point. ORC is very effective in utilizing heat sources with low to moderate temperatures, such as those often found in geothermal energy sources in

Indonesia. The ORC can operate at lower temperatures than traditional Rankine cycles, with operating temperatures typically ranging from 80°C to 150°C. Flexibility in the selection of working fluids allows the ORC to be optimized according to the conditions of the available heat source. ORC is also known for its high efficiency in converting heat from energy sources with temperatures below 150°C into electrical energy, making it an excellent choice for geothermal applications in Indonesia.

However, the development of low-enthalpy geothermal energy in Indonesia still faces major challenges due to the limitations of available technology. Although the potential of this low-enthalpy energy is large, the technology needed to utilize it is still not widely developed, even though this potential can be a significant solution to the needs of renewable energy in Indonesia. The combination of the Kalina KCS-34 Cycle and the Organic Rankine Cycle (ORC) offers an opportunity to overcome this challenge, by leveraging the advantages of each technology to maximize the efficiency of geothermal resource utilization in Indonesia. In an effort to answer the challenge of developing geothermal energy, especially for low enthalpy energy in Indonesia, we are developing an innovation that combines two cycles, namely the Kalina KCS-34 Cycle and the Organic Rankine Cycle (ORC). This innovation aims to overcome technological barriers that currently limit the exploration and utilization of geothermal resources in Indonesia. This innovation is designed to maximize the potential of low enthalpy geothermal energy through a more efficient, economical, and environmentally friendly approach. With the application of advanced technology and innovative approaches, this innovation is expected to be able to increase the use of geothermal energy more widely and sustainably in Indonesia, as well as support the national target of increasing the portion of renewable energy in the energy mix.

2. THERMODYNAMIC ANALYSIS

Equipment such as turbines, pumps, compressors, and heat exchangers are examples of open systems. An open system is a system in which there is an exchange of energy (in the form of heat and work) as well as mass with the surrounding environment. In this system, both mass and energy can cross the boundaries of a permeable system. In other words, an open system allows the masses to enter and exit the system. As a result, the system volume remains unchanged, so it is often referred to as the control volume. This control volume is an area set to facilitate the analysis of the flow of mass and energy that occurs. Thus, in this system, the volume of the system does not change so it is also called volume control. Volume control is a restriction of the review area on a component to facilitate calculations in more detail. The energy transfer at the volume control limit occurs in the form of work and heat. In Figure 1. It can be seen that in the inlet (i) is the flow of mass into the control volume and exit (e) is the flow of mass out of the control volume. In the control volume, two laws apply, namely mass conservation and energy conservation.

$\frac{dE_{cv}}{dt}$ =A<a0>i – Áe ṁe ..... (1.1)

$$\frac{de_{cv}}{dt} = \dot{Q} - \dot{w} + \dot{m}_i\left(u_i + \frac{V_i^2}{2} + gz_i\right) - \dot{m}_e\left(u_i + \frac{V_e^2}{2} + gz_e\right) \quad \text{..... (1.2)}$$

Assuming that the work of the incoming fluid is considered negative and the work of the outgoing fluid is positive, the notation Ẇ in equation 1.2 indicates the force affected by the work of the incoming fluid (Ẇi) and the outgoing fluid (Ẇe) passing through the control volume. The power of Ẇ can also be described as the product of force (F) and velocity (V). This force itself is the result of the multiplication between the pressure (p) and the surface area that receives the pressure (A). In addition, Ẇ is also affected by the conditions around the control volume, such as shaft rotation, mass and energy transfer from the control volume limit, as well as electrical effects, denoted as Ẇcv. Thus, Ẇ can be formulated as shown in equation 1.3.

$$\dot{w} = \dot{w}_{cv} + \dot{w}_e - \dot{w}_i$$

$$\dot{w} = \dot{w}_{cv} + (p_e A_e)V_e - (p_i A_i)V_i \quad \text{..... (1.3)}$$

With AV = ṁv, then equation 1.3 becomes equation 1.4.

$$\dot{w} = \dot{w}_{cv} + \dot{m}_e(p_e v_e) - \dot{m}_i(p_i v_i) \quad \text{..... (1.4)}$$

Equation 2.4 is substituted in equation 1.2 so that it becomes equation 2.5.

$$\frac{de_{cv}}{dt} = \dot{Q}_{cv} \text{ -) -)} \quad \text{..... (1.5)} \dot{W}_{cv} + \dot{m}_i(u_i + p_i v_i + \frac{V_i^2}{2} + gz_i \dot{m}_e(u_e + p_e v_e + \frac{V_e^2}{2} + gz_e$$

The subscript "cv" is added to Q̇ to emphasize that the rate of heat transfer occurs at the boundary of the control volume. Equation 1.5 can be written using the specific enthalphy (h) where h = u + pv. Then equation 1.5 becomes equation 1.6.

$\frac{de_{cv}}{dt} = \dot{Q}_{cv}$ -) -) ..... (1.6) $\dot{W}_{cv} + \dot{m}_i(h_i + \frac{V_i^2}{2} + gz_i \dot{m}_e(h_e + \frac{V_e^2}{2} + gz_e$

In the actual state there may be several locations around the boundary that are traversed by the flow of incoming or outgoing mass, thus equation 1.6 becomes equation 1.7.

$\frac{de_{cv}}{dt} = \dot{Q}_{cv}$ -) -) ..... (1.7) $\dot{W}_{cv} + \sum_i \dot{m}_i (h_i + \frac{V_i^2}{2} + gz_i \sum_e \dot{m}_e (h_e + \frac{V_e^2}{2} + gz_e$

The volume control condition is assumed to be steady state to make the calculation process easier. A steady state is an ideal state which means that all properties do not change with time. Likewise, the rate of mass flow, the rate of thermal energy transfer, and work also do not change with time. Therefore, in the principle of the law of mass conservation in equation 1.1 can be equation 1.8.

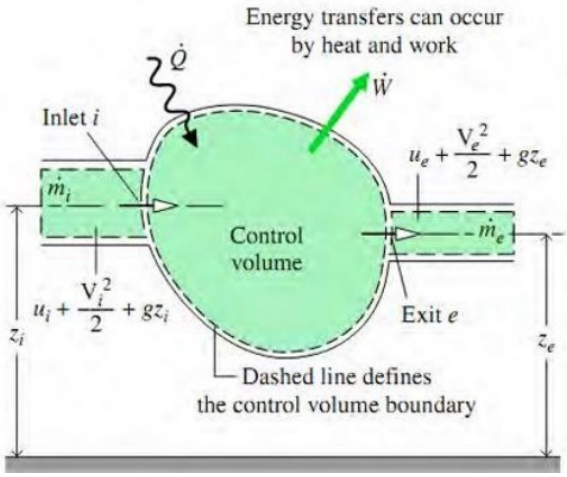

Figure 1: Volume Control Illustration.

$\frac{dE_{cv}}{dt}$ =Ai ṁi – Σe ṁe ..... (1.8)
0 = Σi ṁi – Σe ṁe
Ci = Ṁi = Σe ṁe

As well as on the principle of energy conservation in a steady state, equation 1.2 can be equation 1.9.

$\frac{dE_{cv}}{dt} = \dot{Q}_{cv} - \dot{W}_{cv} + \dot{m}_i(h_i + \frac{V_i^2}{2} + gz_i)$ - Σe ṁe (he + + gz$\frac{V^2_e}{2}$e) ..... (1.9)

$0 = \dot{Q}_{cv} - \dot{W}_{cv} + \dot{m}_i(h_i + \frac{V_i^2}{2} + gz_i)$ - Σe ṁe (he + + gz$\frac{V^2_e}{2}$e)

Qcv – Wcv + Σi ṁi (hi + + gz$\frac{V^2_i}{2}$i) = Σe ṁe (he + + gz$\frac{V^2_e}{2}$e)

3. DISCUSSION

In the midst of the global climate crisis, the world is increasingly shifting to renewable energy with low carbon emissions, with geothermal energy being one of the solutions. Indonesia, thanks to its position at the confluence of tectonic plates, has abundant geothermal reserves. According to the Geological Agency of the Ministry of Energy and Mineral Resources, Indonesia has a geothermal energy potential of 29,215 MW, or around 40% of the global geothermal potential. High enthalpy geothermal, with temperatures above 200°C, is commonly found in active volcanic regions such as West Java and North Sumatra, suitable for large-scale power plants using technologies such as Flash Steam Power Plants. Meanwhile, the enthalpy geothermal medium, with temperatures between 100°C to 200°C, is often utilized for cogeneration, with significant potential in areas such as Dieng, Central Java. Low enthalpy geothermal, with temperatures below 100°C, is distributed in non-volcanic areas such as South Sumatra and Nusa Tenggara, and can be optimized for small-scale power plants using technologies such as Organic Rankine Cycle (ORC) and Kalina Cycle System (KCS).

Geothermal energy is also classified based on the depth of its heat source. Shallow geothermal, which comes from the earth's layers closer to the surface, is often used for heating and cooling systems through Ground Source Heat Pumps (GSHP) technology. While deep geothermal, from a deeper layer, is more suitable for power plants with high temperatures to drive turbines. Geothermal applications in Indonesia vary, ranging from power plants with technologies such as Flash Steam, Binary Cycle, and Dry Steam Power Plants to direct applications such as space

heating, drying agricultural products, and heating fish ponds. With its wealth of geothermal resources, Indonesia has a great opportunity to develop renewable energy and reduce carbon emissions, optimizing the potential spread throughout the region, both volcanic and non-volcanic.

3.1. 2-Cycle Merger

In the world of geothermal energy generation, the two most well-known and frequently used cycles are the Organic Rankine Cycle (ORC) and the Kalina Cycle System (KCS) 34. Although both are designed to efficiently utilize the heat energy from the low enthalpy source, these two cycles usually operate separately due to the differences in the characteristics of the working fluid and its operational principles. However, in the midst of the need for innovation in the use of renewable energy, the idea of combining the advantages of these two cycles into one new system has emerged. This innovation is designed to optimize efficiency and flexibility in the utilization of low enthalpy geothermal resources, by integrating the best aspects of ORC and Kalina KCS 34. The merger aims to create a more adaptive and effective power generation system, which can make better use of the variety of heat sources and generate greater energy output. This innovation is a step forward in geothermal technology, offering innovative solutions to the energy challenges of the future.

3.1.1. Integrated System Design

ORC uses organic fluids with a lower boiling point than water, so it can operate efficiently at lower temperatures. The integration of the ORC with the KCS 34 allows for more effective heat recovery from low-enthalpy geothermal sources. The design of an integrated system must take into account the thermal properties of both cycles. A good heat exchanger network is essential to ensure efficient heat transfer between the two cycles. This requires detailed thermal analysis and simulation to optimize system configuration.

3.1.2. Practical Analysis

This paper presents innovative solutions to utilize low enthalpy energy using a combined Kalina and ORC system including its practical applications. Geothermal power plants in regions with low- to medium-temperature heat sources (120-150°C) can benefit from the combined Kalina-ORC system. For example, in Indonesia, which has many geothermal sources with these temperatures, this combined system allows for higher efficiency in electricity generation, so that it can generate more energy by utilizing existing resources.

Case Study: In Wayang Windu, Indonesia, the implementation of the Kalina-ORC joint system allowed for an increase in electricity output without major investment in new infrastructure. Total efficiency increased by up to 18%, which significantly reduces the cost per kWh of electricity generated by wind power with wildlife detection, wind power with wildlife detection, offshore wind power, where underwater structures and wind farms function as artificial reefs.

3.2. Merge System Analysis

Equipment such as turbines, pumps, compressors, and heat exchangers are examples of open systems. An open system is a system in which there is an exchange of energy (in the form of heat and work) as well as mass with its environment. In this system, both mass and energy can cross the boundaries of a permeable system. In other words, an open system allows the flow of mass in and out of the system. Therefore, the volume of the system remains constant, so it is also called the control volume. This volume control is a boundary area that is set to facilitate the analysis of the flow of mass and energy that occurs.

3.2.1. Modeling and Simulation Results

Figure 2 shows a process flow diagram of a thermal energy generation system involving a combination of components such as gas turbines, pumps, heat exchangers, and cooling systems.

Here is a brief description of the components and energy flows in the system:

Compressor (K-100): Air (Air Feed) is compressed by this compressor with an energy input of Q comp The high-pressure air is then flowed to the turbine components for the combustion process. Combustor: Fuel gas is mixed with high-pressure air in the combustion chamber (Combustor). The heat generated from this combustion is used to rotate the turbine. Gas Turbine (CRV-100): The gas turbine produces a power of 5972 kW with a heat flow of 2,150 × 107 kJ/h This energy is the main output of the generation system.

Heat Exchangers (K-101, K-102, E-101): After passing through the turbine, the hot exhaust gases are passed through several heat exchangers to heat the water and produce steam that will be used for additional work, or for further processing. The system is designed to optimize the use of heat from gaseous fuel and harness that energy to generate electricity. The system is designed to optimize the use of heat from gaseous fuel and harness that energy to generate electricity. The thermal efficiency of the gas turbines used is one of the main focuses in this analysis

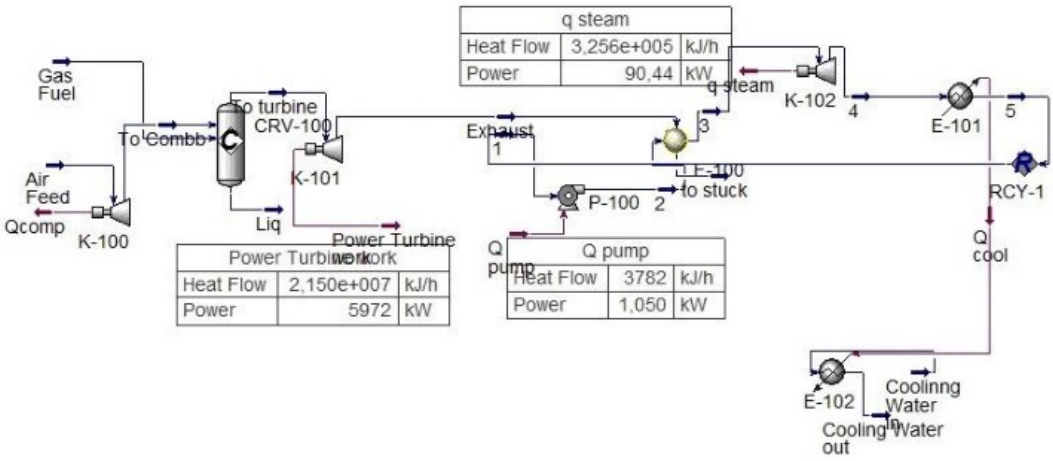

Figure 2: Results and Simulations.

The system demonstrates the efficient distribution of energy between power production through turbines and residual heat management. The measured heat flow at multiple points shows how thermal energy is processed and distributed along the system The Cooling System helps to remove excess heat from the working fluid, ensuring that the system remains in safe and efficient operating conditionsBy using fuel gas as the main energy source and utilizing efficient gas turbine and heat exchanger technology, the system has the potential to reduce carbon emissions. The utilization of residual heat also helps in reducing the need for additional fuel, which directly reduces the carbon footprint of the plant's operations. A combined system involving a gas turbine, heat exchanger, and cooling system as shown in the image is an effective solution for efficient and low-emission energy generation. With the optimal utilization of residual heat and energy distribution, these systems can provide significant power output while minimizing environmental impact. However, to achieve maximum results, these systems require careful design and careful maintenance.

3.2.2. Pressure Analysis on Turbines

The cycle modeling of KCS 34 and ORC that has been simulated with no errors and waring is coupled with the simulation of various variations. This variation was carried out at the fluid pressure at the turbine inlet with a pressure of 2 bar, 5 bar, 7 bar, 9 bar, and 11 bar at an ammonia-water mass fraction of 85.8%. From these variations the power generated by each variation and the quality of the steam coming out of the turbine from each pressure. The following is a table of data resulting from the variation in pressure obtained:

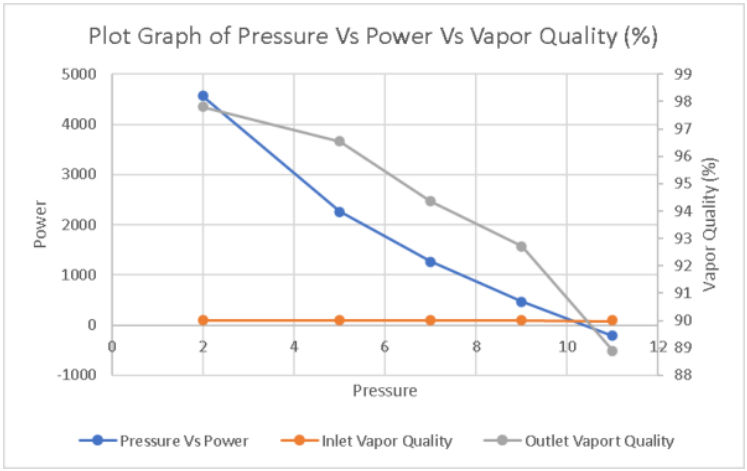

Figure 3: Pressure vs Power vs Steam Quality Chart Plot (%).

The graph shows that there is a negative correlation between pressure and power generated by the geothermal system. At lower pressures, the power produced reaches a maximum figure of around 5000 MW. However, as the pressure increases to 12 MPa, the power decreases significantly to near zero.

This decrease can be explained by thermodynamic theory where an increase in pressure in a geothermal system leads to a decrease in turbine efficiency. This is due to the fact that at higher pressures, the steam produced tends

to be more saturated with water. This saturated steam has a higher density and a smaller specific volume, thus reducing the ability of the steam to perform mechanical work on the turbine

The graph also displays two lines that show the quality of the steam at the inlet and outlet points of the system. The quality of the steam inlet is relatively stable at around 90%, indicating that the condition of the steam entering the system is quite consistent. However, the quality of the outlet steam has decreased significantly along with the increase in pressure.

At low pressure, the steam quality of the outlet reaches about 98%, but decreases to about 90% at the highest pressure measured. This decrease in quality indicates that some of the steam turns into water as the pressure increases, which in turn can decrease the efficiency of the system and increase the potential for damage to the turbine due to erosion and corrosion.

From the graph, it can be concluded that pressure has a significant influence on the power generated and steam quality in geothermal systems with low enthalpy energy. To achieve maximum efficiency, the system must be operated at optimal pressure, where the power generated is high enough and the quality of the steam is maintained above a certain threshold to prevent damage to the system components.

The system design also needs to consider pressure control and steam quality management to maximize the efficiency and longevity of the equipment. In addition, the use of steam separation or steam drying technology may be necessary to maintain high steam quality at various operating pressures.

3.2.3. Analysis of Variation in Fluid Mass Fraction at 22 Bar Pressure

In the table below there are seven variations of the mass fraction with the power produced and the quality of the turbine output steam from each variation of the mass fraction. Then from the table above, Figure 4 is obtained, which is a graph of the influence of mass fraction on the power and quality of turbine output steam at a pressure of 22 bar. Figure 4 is a trend of the cyclic power graph of Kalina KCS 34 and ORC of the quality of turbine output steam due to the influence of the fluid mass fraction at a pressure of 22 bar.

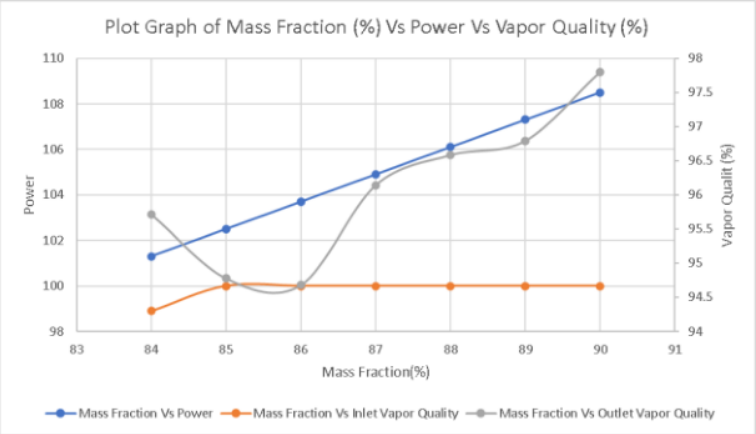

Figure 4: Mass Fraction Chart (%) vs Power vs Steam Quality (%).

The graph above shows the relationship between fraction, power, and steam quality at inlets and outlets in a thermodynamic system. This analysis refers to how changes in fractions affect system performance, especially on the power generated and steam quality. The blue line in the graph shows the relationship between fractions and power. Along with the increase in fraction from about 84 to 90, there is a consistent increase in power. This signifies that an increase in fraction, which may be related to the amount of fuel or the mass of the flow of the working fluid, results in greater power. This significant increase in power indicates better energy conversion efficiency, where energy stored in fuel or working fluid is converted into more effective mechanical work. This is in line with the principle of thermodynamics that an increase in energy input (in this case a fraction) can result in a higher energy output, depending on the efficiency of the system (Cengel & Boles, 2015). The orange line depicts the relationship between the fraction and the quality of the steam on the inlet. Interestingly, this line is almost flat, indicating that the increase in fraction does not significantly affect the quality of the steam at the inlet, which is stable at around 95.4% to 95.5%. This stability may be due to the operating conditions of the system that remain constant on the inlet section, so that the quality of the steam does not change much even though the fraction increases (Moran & Shapiro, 2010). This suggests that other variables such as temperature or inlet pressure may be more dominant in determining steam quality at this point, while fractions have a more minimal impact.

The gray line shows the relationship between the fraction and the quality of the steam at the outlet. It can be seen that in the fraction of about 85, the quality of steam decreases slightly, but then increases as the fraction increases.

The overall steam quality at the outlet improved from about 95% to almost 98% when the fraction increased from 84 to 90. This increase can be due to improvements in heat transfer or increased efficiency of the vapor change phase as the fraction increases. The temporary decline in fraction 85 may be due to changes in suboptimal operating conditions, but the general trend continues to show an improvement in steam quality indicating an improvement in thermodynamic efficiency (Incropera et al., 2007). From the analysis of this graph, it can be concluded that the increase in fraction has a positive impact on the power generated and the quality of steam at the outlet. The steam quality at the inlet tends to be stable and is not much affected by fractional changes, which signals the need for further analysis on other variables that may further affect the steam quality at that point. These findings support the importance of fraction optimization in the system to achieve better overall performance.

3.3. Economic Analysis

To evaluate the financial feasibility of the application of the low enthalpy geothermal heat pump technology shown in the figure, we will conduct an economic analysis that includes the calculation of initial costs, operational costs, and energy savings generated. In addition, we will also calculate the Return On Investment (ROI) and potential savings in the long term.

3.3.1. Financial Analysis

The initial cost includes the purchase and installation of the main equipment in the system, such as compressors, turbines, heat exchangers, pumps, and cooling systems. These cost estimates can vary depending on the scale of the project and geographic conditions. Here are the main components of the initial cost:

- Compressor (K-100): The cost for an industrial compressor with the capacity as shown in the figure can range from USD 200,000 to USD 500,000, depending on its capacity and efficiency.
- Gas Turbine (CRV-100): A gas turbine with a capacity of about 5 MW can require an investment cost of around USD 1.5 million to USD 2.5 million.
- Heat Exchanger (K-101, K-102, E-101): The cost for a heat exchanger ranges from USD 100,000 to USD 300,000 per unit, depending on the design and material.
- Pump (P-100): A pump with the indicated capacity can cost around USD 50,000 to USD 150,000.
- Refrigeration System (E-102, RCY-1): An efficient refrigeration system can cost an investment of around USD 100,000 to USD 300,000.

If we take the highest cost estimate for each component, the total initial cost can reach around USD 3.95 million to USD 4.75 million.

3.3.2. Cost Estimation Analysis

Operational costs include energy costs, routine maintenance, and replacement of necessary components during the operational period. Here is an estimate of the annual operating costs:

- Energy for Compressor and Pump Operation: Assuming the energy consumption of the compressor and pump corresponds to the given power value (5972 kW for turbines and 1050 kW for pumps), and with an average commercial electricity tariff of USD 0.10 per kWh, the annual energy cost can be calculated as follows:

  Annual Energy Cost = ((5972+1050) kW × 8760 hours/year) × $0.10/kWh
  Annual Energy Cost = 7,022,160 kWh × $0.10/kWh
  Annual Energy Cost = $702,216/year
  Annual Energy Cost=7,022,160kWh×0.10USD/kWh=702,216USD/year

- Maintenance and Replacement of Components: This cost can be about 2-3% of the initial cost per year, so it is about USD 100,000 to USD 150,000 per year.
- Estimated Total Annual Operating Costs are approximately USD 802,216 to USD 852,216 per year.

3.3.3. Energy Savings

Assuming that this system produces energy with 45% higher efficiency compared to conventional systems, and that a comparable conventional system requires an energy cost of USD 1.2 million per year, the annual energy savings can be calculated as follows:

Annual Energy Savings = $1.2 million × 0.45

Annual Energy Savings = $540,000/year

Annual Energy Savings = $1.2 million × $0.45 = $540,000/year

3.3.4. Return On Investment (ROI)

ROI = Annual Savings / Total Initial Investment × 100%

ROI = $540,000/year /$4.75 million ×100% = 11.37%

3.3.5. Payback Period

The payback period is the time it takes to recoup the initial investment through energy savings. This can be calculated as:

Payback Period = Total Initial Investment/Annual Savings

Payback Period = 4.75 million USD = 540,000 USD/year ≈ 8.8 years

However, if we take into account annual operating costs, the actual payback period may be longer, around 9-10 years, depending on the actual operating costs and savings achieved.

3.4. Application in Various Sectors

To compare the thermodynamic performance of the combined system shown in the figure above with the Kalina KCS 34 cycle and the Organic Rankine Cycle (ORC), we will perform an analysis based on energy efficiency, thermal output, and carbon emissions. Here is a detailed comparison of the three systems.

3.4.1. Energy Efficiency

- Combined System

  The combined system shown in the figure uses a combination of thermal cycles, which involves a gas turbine, a heat exchanger, and a cooling system. The energy efficiency of these systems depends on the optimization of heat transfer and turbine performance. With a turbine producing around 5972 kW of power and a heat exchanger that utilizes waste heat to generate additional energy, the efficiency of this system is quite high, mainly due to the reuse of waste heat.

- Kalina KCS 34

  The Kalina KCS 34 cycle is a thermodynamic cycle that utilizes an ammonia-water mixture as a working fluid. This allows for heat utilization at various temperature levels with higher efficiency than conventional ORC. Kalina cycles typically achieve higher thermal efficiency, about 10-15% more efficient than ORCs, especially in applications with heat sources ranging from medium to low temperatures. In the case of Kalina KCS 34, thermal efficiency can reach up to 50-55%, depending on the conditions of the heat source.

- Organic Rankine Cycle (ORC)

  ORC uses an organic fluid with a low boiling point to generate power from a heat source that is not high enough for a standard Rankine cycle. ORC is often used in low to medium temperature heat sources and is known to have lower thermal efficiency than the Kalina cycle, with a range of

- Comparison

  Energy Efficiency: Kalina KCS 34 > ORC > Combined System

  The Kalina KCS 34 cycle has the highest energy efficiency due to its ability to utilize various temperature levels, followed by a combined system that reuses waste heat, and finally an ORC that has lower efficiency.

3.4.2. Output Termal

- Combined System

  This system shows the thermal output of various components such as turbines and heat exchangers. With a waste heat value of 2.15 kJ/h from the turbine and a heat output of 3,256 kJ/h from the heat exchanger, the system makes optimal use of the waste heat to generate additional thermal output, which can be used for heating applications or additional energy production.

- Kalina KCS 34

  The Kalina cycle can produce significant thermal output due to its ammonia-water working fluid which allows the utilization of heat energy at various temperature points. The thermal output of the Kalina KCS 34 cycle is often greater than that of ORC due to the more flexible and efficient nature of the working fluid in utilizing the heat source.

- Organic Rankine Cycle (ORC)

  ORC tends to have a lower thermal output compared to combined and Kalina cycle systems due to limitations in the utilization of heat sources at low temperatures. Nonetheless, ORC is more commonly used in applications where simplicity and low cost are a priority, even if the thermal output is not as large as other systems.

- Comparison

  Thermal Output: Kalina KCS 34 > > Combined System

  Combined systems, with the utilization of waste heat from multiple sources, tend to produce greater thermal output than Kalina KCS 34 and ORC cycles

3.4.3. Carbon Emissions

- Combined System

  By reusing waste heat, this system has the potential to reduce carbon emissions compared to systems that rely solely on fossil fuels. With high energy efficiency, the carbon emissions from these systems are relatively low, especially when compared to fossil fuel-based systems that do not utilize waste heat.

- Kalina KCS 34

  The Kalina cycle is known to have lower carbon emissions due to its higher efficiency in utilizing thermal energy. Thus, the energy use per unit of output is lower, which directly reduces carbon emissions. The Kalina cycle is commonly used in power plants that want to maximize efficiency while minimizing environmental impact.

- Organic Rankine Cycle (ORC)

  Although ORCs have lower thermal efficiency, carbon emissions from ORCs can also be minimized if these systems are combined with renewable heat sources, such as waste heat from industrial processes or geothermal sources. However, compared to the Kalina KCS 34 and the combined system, the carbon emissions from the ORC can be higher due to the lower efficiency.

- Comparison

  Carbon Emissions: Kalina KCS 34 < Combined System < ORC

  The Kalina KCS 34 cycle has the lowest carbon emissions due to higher energy efficiency, followed by the combined system, and finally the ORC.

3.4.4. Comparison Results

In terms of thermodynamics, the Kalina KCS 34 cycle shows superior performance with the highest energy efficiency and lowest carbon emissions, especially in applications with medium to low temperature heat sources. The combined system, as depicted in the image above, offers a good balance between energy efficiency and thermal output, as well as a reduction in carbon emissions through the reuse of waste heat. ORCs, despite their lower efficiency, remain a viable option in situations where design simplicity and low cost are preferred.

For applications where energy efficiency and carbon emission reduction are top priorities, the Kalina KCS 34 cycle is more recommended. However, if flexibility in the utilization of waste heat and large thermal output are required, a combined system can be the best option. ORC can be selected for small-scale applications with renewable heat sources.

3.5. Application in Various Sectors

Indonesia, with its abundant geothermal potential, is at the forefront of efforts to utilize renewable energy sources for future energy needs. In particular, low enthalpy geothermal, known for its low temperatures, presents a great opportunity for the development of innovative technologies that can address renewable energy challenges in various sectors. This innovation, as we have developed through an integration system that combines the advantages of the ORC cycle and Kalina KCS is one of the breakthrough efforts to improve efficiency and flexibility in the utilization of geothermal energy.

This innovation opens the door to a wider range of applications of geothermal low enthalpy, not only in small-scale power plants, but also for direct applications in the industrial, agricultural and tourism sectors. By optimizing this technology, we can be more efficient in using geothermal resources scattered throughout the country, both in volcanic and non-volcanic regions. These innovations allow the use of energy for drying agricultural produce,

heating fish ponds, and even spa facilities in the tourism industry, at lower costs and minimal environmental impact.

In the following sections, it will be explained in more detail how this technology can be applied in Indonesia's key sectors, as well as how the integration of these innovations can provide solutions to sustainable energy needs. This discussion will cover the technical aspects of the implementation of the integrated system, as well as its impact on energy efficiency and contribution to the national renewable energy target. Thus, we can see the whole picture of how innovation in low enthalpy geothermal can be the answer to Indonesia's future energy challenges.

3.6. Implementation Strategy

In an effort to utilize technology low enthalpy geothermal Effectively, it is important to develop a comprehensive implementation strategy. This strategy should include adequate technical planning, supportive regulatory arrangements, and identification of challenges that may arise. Technical needs involve the selection and installation of appropriate technologies, while regulations must ensure policy support and incentives. Challenges that may be faced include technical constraints, adaptation to local conditions, and harmonious arrangements with existing energy regulations. With a planned strategy, this technology can be effectively integrated to support sustainable energy growth in Indonesia.

3.6.1. Technical Requirements

The application of low enthalpy geothermal technology in Indonesia requires the right selection of technology and efficient system design, such as ORC that is effective at low temperatures and KCS that uses ammonia-water mixtures to improve efficiency. Supporting infrastructure is also crucial, including geothermal wells designed for heat extraction efficiency, power distribution networks to connect plants with end-users, and processing and maintenance facilities to maintain optimal operations. Given Indonesia's varied geological conditions, the design of the system must be adapted to geothermal potential and local challenges, such as accessibility and environmental impacts, to ensure maximum benefits from these technologies.

3.6.2. Regulation

To ensure that the application of geothermal low enthalpy technology runs effectively and in accordance with the provisions of the law in Indonesia, an understanding of the regulations governing the geothermal sector is very important. Law Number 21 of 2014 concerning Geothermal and Government Regulation Number 7 of 2017 are the main legal basis that includes sustainable management, efficiency, and support for technological innovation. Articles in this law, such as Article 3 which establishes national energy development goals and Article 4 which emphasizes sustainable management, support the development of this technology, which integrates ORC and KCS-34 to improve energy efficiency. Government regulations also provide incentives and ease of licensing for research and development of geothermal technology. Support from local regulations and local government policies further facilitates the application of geothermal technology in areas with high potential. Overall, the regulatory framework in Indonesia provides a strong foundation for the development and implementation of efficient and environmentally friendly geothermal innovations.

3.7. Analysis of possible challenges at the time of implementation

The implementation of low enthalpy geothermal technology in Indonesia faces several main challenges, both technical, infrastructive, social, and environmental. Technically, geological variability and technological adaptations such as ORC and KCS 34 to local conditions require accurate geothermal evaluation and system adjustment. In terms of infrastructure, the construction of drilling wells and electricity distribution systems in remote areas requires complex costs and logistics. In addition, electricity grid connectivity is also an obstacle, especially in areas with inadequate infrastructure. Social challenges include the acceptance of local communities, which requires effective socialization to gain support and reduce conflict. On the environmental side, although geothermal energy is relatively clean, large projects still have the potential to cause environmental impacts that require careful mitigation. Facing and responding to these challenges with the right strategy will ensure that the implementation of this technology runs efficiently and provides significant benefits for the development of renewable energy in Indonesia.

4. STUDY CASE

To reinforce the thermodynamic analysis that has been carried out previously, we will add relevant case studies regarding the application of the Kalina KCS 34 system, ORC, and combined system as shown in the figure. This case study will provide insight into how these technologies are applied in real-world situations and how they perform under various operational conditions.

4.1 Case Study 1: Geothermal Power Plant with Kalina KCS 34 Cycle in Chena, Alaska

Background:

The Geothermal Power Plant in Chena, Alaska, is one of the most well-known examples of the use of the Kalina KCS 34 cycle to utilize low-temperature geothermal sources. Chena Hot Springs, with a heat source temperature of around 74°C, is an ideal location for the testing and application of Kalina KCS 34, which is designed for high efficiency with a low-temperature heat source.

Implementation and Results:

The power plant uses the Kalina KCS 34 cycle, which is capable of converting low-temperature geothermal heat into electricity with significant efficiency. The system is capable of achieving thermal efficiency of about 45%, much higher compared to standard ORC under similar conditions, which typically has an efficiency of around 20-30%. With an electrical output of around 400 kW, the plant has proven that the Kalina KCS 34 can be operated stably and efficiently in extreme environmental conditions, such as the one in Alaska. In addition, because these systems reduce reliance on fossil fuels, carbon emissions are significantly reduced.

Lessons to Take:

This case study shows that Kalina KCS 34 is very effective in utilizing low-temperature heat sources, and can be used in remote locations with limited infrastructure. Its high efficiency and reduced carbon emissions make it an excellent solution for regions looking to maximize the use of renewable energy sources while minimizing environmental impact.

4.2 Case Study 2: ORC Implementation in a Geothermal Power Plant in Neustadt-Glewe, Germany

Background:

The power plant in Neustadt-Glewe is another example of the use of ORC technology to utilize low- to medium-temperature geothermal sources. The plant uses ORC to utilize a heat source with a temperature of around 98°C.

Implementation and Results:

The ORC system applied here uses organic fluids as a working medium that has a low boiling point, allowing the conversion of geothermal energy into electricity with an efficiency of about 10-20%, depending on the operating conditions. The electricity output from this plant is about 210 kW. Although the efficiency is lower compared to the Kalina cycle, the ORC system has advantages in terms of simple design, lower initial cost, and the ability to be easily integrated into existing systems.

Lessons to Take:

ORCs are ideal for small to medium-scale applications, especially in locations that require energy solutions with lower initial costs. However, the lower efficiency means that in the long run, ORC may result in smaller energy savings and a greater environmental impact compared to the Kalina cycle.

4.3 Case Study 3: Combined Systems at an Industrial Plant in California

Background:

An industrial plant in California has implemented a combined system similar to the one shown in the image above. The system utilizes the exhaust heat from the gas turbine to improve the overall efficiency of the plant.

Implementation and Results:

In this case, the plant uses a gas turbine with an output of 5 MW for the industrial process, and the waste heat from the turbine is used in the heat exchanger system to heat additional working fluids which are then used to generate more energy or for further heating processes in the plant. The system has successfully increased the thermal efficiency of the entire plant by up to 55%, higher than the use of separate gas turbines. In addition, the plant's carbon emissions are also reduced by around 25% thanks to the reuse of waste heat.

Lessons to Take:

Combined systems are particularly beneficial in industrial applications where exhaust heat is often not utilized to its full potential. By using waste heat to improve energy efficiency, the system not only reduces energy consumption but also reduces carbon emissions, making it a highly effective solution in energy saving and environmental protection efforts.

4.4 Conclusion of the Case Study

These three case studies show that each technology has its own advantages and disadvantages:

- Kalina KCS 34 is most effective in utilizing low to medium temperature heat sources with high efficiency and low carbon emissions. It is the best choice for applications in remote locations or places where energy efficiency and carbon emission reduction are prioritized.
- ORC is a more economical option for small to medium-scale applications with a low heat source. Despite their lower efficiency, ORCs offer lower upfront costs and ease of integration with existing systems.
- The Combined System offers high thermal efficiency and optimal utilization of waste heat, making it an ideal choice for industrial applications looking to optimize energy use and reduce carbon emissions.

5. CONCLUSION

The innovation of combining two cycles, namely the Organic Rankine Cycle (ORC) and the Kalina Cycle System (KCS-34), offers a significant solution to utilize low enthalpy geothermal energy in Indonesia. The combination of these two cycles in one integrated system, results in a more efficient and flexible power generation system compared to conventional systems that only use one of the cycles separately.

The analysis of the merging system shows that the integration of ORC and KCS-34 provides higher energy efficiency by making optimal use of waste heat. This combined system is able to maximize the use of heat from geothermal sources with a low to moderate temperature range, so that it can produce a greater thermal output than using an ORC or KCS-34 system independently. Simulations show that the system can operate with about 5,972 kW of power from the turbine and harness the waste heat to generate additional energy.

From economic analysis, this combined system offers promising financial profit potential. The initial cost of the investment may be higher than that of conventional systems, but the Return on Investment (ROI) and Payback Period show that with higher energy savings and better efficiency, the investment can return in a shorter period of time, which is about 8-10 years. In addition, with significant annual savings, the system can provide long-term economic benefits.

Comparative analysis with conventional systems confirms that this combined system has better thermal efficiency compared to the stand-alone ORC and Kalina KCS-34 systems. Additionally, the system has lower carbon emissions thanks to its more effective utilization of waste heat, making it a more environmentally friendly option when it comes to generating electricity from geothermal sources.

The results and simulations show that the design of this system not only improves energy efficiency but also reduces environmental impact and provides more optimal performance under various operating conditions. With more efficient energy distribution and optimal waste heat management, the system has significantly reduced fuel consumption and carbon emissions, which is in line with Indonesia's goal of developing renewable energy sustainably.

The innovative combination of two cycles of ORC and Kalina KCS-34 through this system presents an efficient and environmentally friendly solution for geothermal power generation in Indonesia. With simulation results showing improved energy efficiency and reduced carbon emissions, this innovation has great potential to support the national energy transition towards sustainable renewable resources. The merger of these two cycles is a step forward in geothermal technology that can bring Indonesia closer to the clean and efficient energy target.

Digitalization of Geothermal Plant Facilities

Wasis Hartono

BB (PT ABB Sakti Industri), Jl. Margomulyo No. 44 Kav. E 1-2, Surabaya, Indonesia

wasis.hartono@id.abb.com

Keywords: Geothermal plant, power plant, digitalization, digital solutions, geothermal plant facilities, asset performance management, energy management and optimization, operation optimization, advanced process control, cyber security

ABSTRACT

Bridging the shift from automation to autonomous operation, ABB's integrated digital solutions address key objectives related to assets, operations, and people. While digital transformation enables autonomy in the energy industry, achieving autonomous operations involves managing various complexities, such as extended operation, remote operation, integrated analytics, and augmented operation. Geothermal power generation plants have a complex configuration, with large steam consumption, multiple production wells, multiples turbines and significant variability in steam production due natural variability of the geothermal process.

ABB's Asset Performance Management (APM) solutions help ensure the reliability of geothermal assets, which involves applying latest technologies such as AI/ML to predict equipment issues, and to predict asset or component life more accurately, so that predictive maintenance and future capital investment can be planned further in advance. Part of this approach, ABB addresses critical geothermal assets like heat exchangers, pumps, pipeline, filter or geothermal wells related issues and corresponding failure modes.

The control and optimization of the multiple power generation and steam networks in geothermal production field, especially with multi-sites, is challenging due to the inherent complexity of the field, the significant interactions between process equipment and the continuous disturbances caused by variability in steam generation by the well. Optimization of energy export and minimization of production costs can be achieved consistently through adaptation of digital solution that manage and optimize the energy and processes. The solution is capable of continuously adapting power generation and steam networks operations to the variability in steam production to maximize power generation efficiency and profits. ABB's OPTIMAX-Advanced Process Control for example offers stabilization of steam in the headers and transfer lines and improve ability to manage disturbances with minimal manual intervention. Also, the solution aim is to optimize the operation and improve the benefit, such as via optimal load allocation on steam generation and turbines, reduction of venting and use of pressure reduction valves, automatic minimization or maximization of internal power production considering daily power prices. One key part of whole digital transformation ecosystem is the exchange of data internally as well externally and to ensure the data transfer is safe and secure, where the relevant Cyber Security practices must be in place. ABB's Cyber Security Workplace (CSWP) addresses the cybersecurity aspects of OT/IT convergence, ensuring secure integration. This comprehensive software ecosystem enhances the reliability, efficiency, and intelligence of geothermal facilities. As a technology leader in electrification and automation, ABB is at the core of propelling the energy transition forward. It's range of solutions optimizes power consumption and processes, crucial for stabilizing renewables and mitigating new energy market risks and effective data management provides transparency and actionable insights, driving efficiency and sustainability gains.

1. INTRODUCTION

Geothermal plays important role in considerably emerging part of Indonesia's power generation, particularly from new and renewable energy sources. Indonesia's investment plan for the $20 billion Just Energy Transition Partnership (JETP) calls for rapid growth in renewable energy of all kinds, including geothermal energy.

Geothermal and hydro can supply the grid with steadier and more predictable forms of electricity generation. According to the JETP scenario, by 2030 geothermal (268 projects) and hydro (470 projects) will produce 22% of Indonesia's electricity. To achieve these goals (which are, it must be said, wildly optimistic) both variable and dispatchable renewables need to grow rapidly over the next seven years.

Huge potential success given the experience and involvement from geothermal developer Geo Dipa (government and PLN owned), PERTAMINA, and PLN.

ABB's integrated solutions in automation, excitation, and turbine control as well as instrumentation, electrical systems and advanced optimization packages ensure flexibility and availability for the customer. Digital solutions such as predictive maintenance solutions reduce O&M costs and insights for operational strategies. Another digital

solution for plant performance, especially in steam and power networks, optimizes the energy export and processes.

Example of ABB's works are retrofit and replace Darajat geothermal plant control, through digital technologies and turbine control systems to improve flexibility, reliability, availability and reduce maintenance cost at the two geothermal plants.

Geothermal power generation plants have a complex configuration, with large steam consumption, multiple production wells, multiples turbines and significant variability in steam production due natural variability of the geothermal process.

Bridging the shift from automation to autonomous operation, ABB's integrated digital solutions address key objectives related to assets, operations, and people. While digital transformation enables autonomy in the energy industry, achieving autonomous operations involves managing various complexities, such as extended operation, remote operation, integrated analytics, and augmented operation.

The paper will give brief overview on ABB digital solutions from Asset Performance Management (APM), Energy Management and Optimization OPTIMAX®-Advanced Process Control, and Cyber Security point of views.

2. MANAGING ASSETS THROUGH ABB ABILITY™ ASSETS PERFORMANCE MANAGEMENT (APM)

ABB's Asset Performance Management (APM) solutions help ensure the reliability of geothermal assets, which involves applying latest technologies such as AI/ML to predict equipment issues, and to predict asset or component life more accurately, so that predictive maintenance and future capital investment can be planned further in advance. Part of this approach, ABB addresses critical geothermal assets like heat exchangers, pumps, pipeline, filter or geothermal wells related issues and corresponding failure modes.

2.1 ABB Ability™ Assets Performance Management

ABB Ability™ Asset Performance Management is a scalable enterprise solution that reduces unscheduled maintenance costs by helping the user better understand and predict asset performance. Higher reliability and production efficiency can be achieved by minimizing or eliminating costly, unplanned downtime. It helps the user extract the most value from the assets by avoiding the uncertainties, risks, and costs of ineffective maintenance approaches. Using data-driven decision making, asset performance and maintenance across the entire enterprise can be optimized.

ABB's Asset Performance Management solutions help ensure the reliability of geothermal assets, which involves applying latest technologies such as AI/ML to predict equipment issues, and to predict asset or component life more accurately, so that predictive maintenance and future capital investment can be planned further in advance. Part of this approach, ABB addresses critical geothermal assets like heat exchangers, pumps, pipeline, filter or geothermal wells related issues and corresponding failure modes.

ABB Ability™ Asset Performance Management is next generation AI-Based Asset Performance Management with vendor agnostic, enterprise-grade, and flexible deployments feature. In Condition Monitoring feature (through AssetInsight or APM Predict solution), adding Condition Monitoring on the Edge into existing OT landscape becomes easier as the solution will start prioritizing maintenance activities based on data. It can provide condition monitoring of electrical, rotating, instruments and IT through OT data/sensors and pre-built asset models to monitor known failure modes. It will provide maintenance workplace with detailed real-time information.

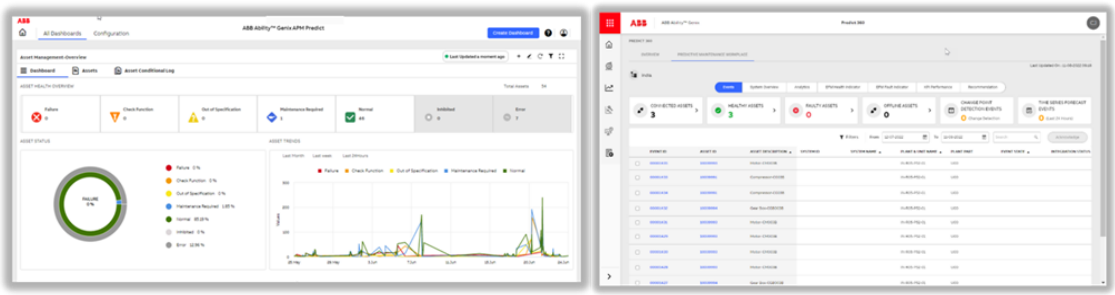

Figure 1: Sample of ABB APM Predict and APM 306 dashboards.

In Advanced Prediction feature (through APM 360), testing, training, and deploying advanced predictive & prescriptive models becomes collaborative by capturing & codifying the knowledge of experts to increase

outcomes. The solution is working with OT/IT/ET contextualized data + derived or predicted parameters, self-service fault modeling throughout asset life cycle, rule-based and AI/ML, library of configurable asset models with pre-built dominant failure modes, and events management, fault monitoring tools with recommendations and automated work order creation.

In Maximum Performance feature (through APM 360), a holistic view of asset performance, health, maintenance schedules, lifecycle cost becomes possible as all it will connect APM, work, operations, and management to realize more value. It works with parametrized asset templates (pre-built performance models), Digital Twin, and 360° view on Performance – Asset Performance, Asset Health, Maintenance Strategy Execution, and Life Cycle Cost.

2.2 Prebuilt asset models

The prebuilt asset models (rule-based or custom logic) in APM built-in library (see Figure 2) are key for conditioning monitoring with real-time fault detection and performance monitoring, single variable threshold monitoring, as well as derived/calculated monitoring. Further the advance predictions are provided by advanced fault modeling and prediction using hybrid modeling techniques. Typically, the 1st Principles physics-based performance models and self-service data driven models using AI/ML algorithms (multi-variate) are incorporated. The Maximum Performance will give asset insights across performance, health, maintenance schedules and life cycle cost by combined & contextualized OT/ET/IT data, Predictive Maintenance Workplace including analytics with CMMS data (as applicable).

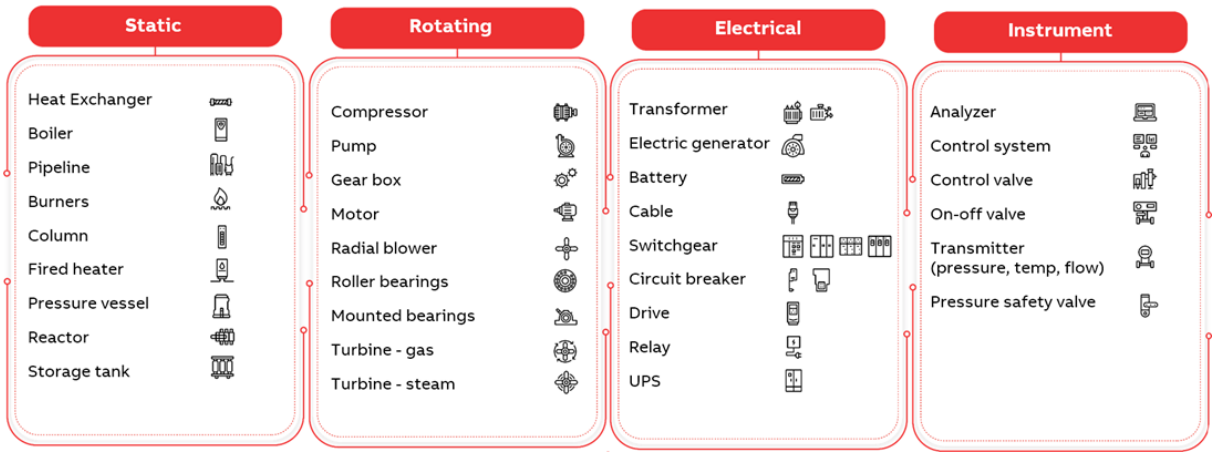

Figure 2: ABB APM's library of pre-built asset models based on domain experience.

In today's rapidly evolving industrial landscape, the integration of advanced analytics and enhanced Asset Performance Management solutions has become paramount for organizations seeking to optimize operational efficiency, reduce costs, and enhance asset performance.

2.3 Data-driven recommendations and actions for asset maintenance.

ABB's cutting-edge technology of ABB Ability™ Asset Performance Management provides advanced analytics and management of asset performance, which play a pivotal role in driving cost reduction, increasing production efficiency, and optimizing resource utilization. There are various showcases success stories where early alerts from ABB's solutions prevented unplanned equipment failures and optimized operational costs, underscoring the tangible benefits of proactive maintenance strategies. Moreover, the transition from reactive to proactive maintenance, facilitated by ABB's solutions, highlights the importance of leveraging the Industrial Internet of Things (IIoT) revolution to revolutionize asset performance monitoring.

By harnessing advanced Machine Learning and Artificial Intelligence capabilities, ABB's APM solutions continuously monitor asset health, detect potential issues, and trigger alerts for timely intervention. This proactive approach empowers organizations to make data-driven decisions, optimize maintenance schedules, and minimize downtime, ultimately enhancing overall operational efficiency (see Figure 3). The transformative potential of advanced analytics and digital tools in driving industrial transformation, optimizing maintenance strategies, and paving the way for a sustainable and efficient future in the industrial sector is evident.

From a practical standpoint, even the best asset management systems do not rely on equipment and data communications systems alone. They depend on human involvement in a culture of continuous improvement among plant operators, maintenance crews, and plant management derived from statistics, data science, heuristic learning, and other expert knowledge. Some perspective on how to make the transition to digital solutions realistically to be respected as there are issues regarding human acceptance of predictive maintenance and asset

management systems which need to be addressed. Something as small as giving users the ability to tweak automated predictive analytics approaches with their own personal experience can be key to successful initial adoption.

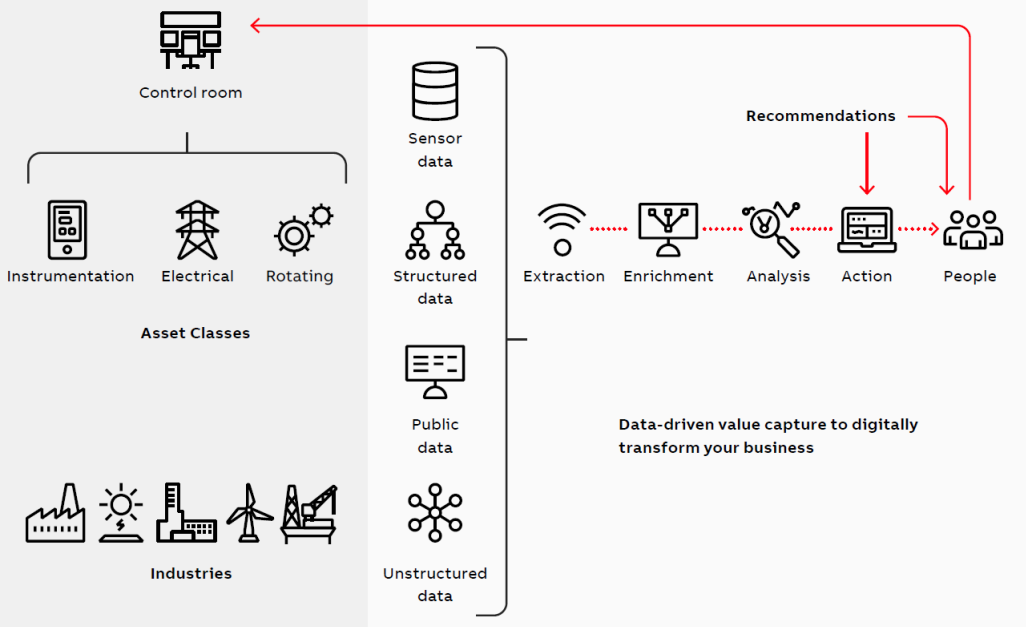

Figure 3: Data driven recommendations and actions in ABB Asset Performance Management application.

The integration of advanced analytics and enhanced Asset Performance Management solutions offered by ABB represents a paradigm shift in industrial operations. By embracing data analytics, artificial intelligence, and digital technologies, organizations can unlock new levels of efficiency, reliability, and sustainability. The journey towards digitalization and enhanced asset performance is not just a technological evolution but a strategic imperative for organizations looking to thrive in the competitive industrial landscape. ABB's commitment to driving innovation and industrial transformation underscores the company's role as a global leader in electrification and automation, shaping a more sustainable and resource-efficient future for industries worldwide, including in geothermal power segment.

3. PERFORMANCE OPTIMIZATION THROUGH ABB ABILITY™ ENERGY MANAGEMENT AND OPTIMIZATION - OPTIMAX® AND ADVANCED PROCESS CONTROL (APC)

The control and optimization of the multiple power generation and steam networks in geothermal production field, especially with multi-sites, is challenging due to the inherent complexity of the field, the significant interactions between process equipment and the continuous disturbances caused by variability in steam generation by the well.

Optimization of energy export and minimization of production costs can be achieved consistently through adaptation of digital solution that manage and optimize the energy and processes.

3.1 ABB Ability™ Energy Management and Optimization – OPTIMAX®-Advanced Process Control

The solution is capable of continuously adapting power generation and steam networks operations to the variability in steam production to maximize power generation efficiency and profits. ABB's OPTIMAX®-Advanced Process Control offers stabilization of steam in the headers and transfer lines, implement optimal load allocation and resulting steam transfer, and improve ability to manage disturbances and balance variability with minimal manual intervention.

The solution is also aimed to optimize the operation and improve the benefit, such as via optimal load allocation on steam generation and turbines, reduction of venting and use of pressure reduction valves, automatic minimization or maximization of internal power production considering daily power prices.

In case of steam turbine optimization, steam turbine efficiency curves can be considered or adopted in the configuration, as well as other parameters such as transfer line losses and equipment constraints. The solution will favor the most favorable load allocation, allowing production maximization and optimization of power revenues and stabilize pressure across all headers and transfer lines, reducing metal stresses, steam losses and variability in operations liked to personnel experience.

Additional benefits from the solution, such as the ability to stabilize operations, reduce manual, actions and standardize operations are also obvious.

3.2 Advanced Process Control underlying technology

The digital solution will be covering the Power Generation and Steam Networks in its application configuration. It will manage the relevant equipment and will operate so to optimize operations and referred here as the "power generation optimization" or "steam and power optimization". It applies the Advanced Process Control (APC) and Energy Optimization application covering the coordination of the geothermal power generation plant.

Advanced Process Control (APC) is a Model-based Predictive Control (MPC) which both actually have a slightly different technical meaning. In a simplified view, MPC describes the technology more accurately while APC is a term often describing a broader set of technologies, which could range from Advanced Regulatory Control in the DCS to full-blown Model Predictive Control technologies. However, in industrial context the APC and MPC acronyms are very often considered equivalent or close to equivalent.

Traditionally, Advanced Process Control relies on Model Predictive Control technology and moving horizon estimation strategies that use either a linear or non-linear mathematical model of the industrial plant and smart algorithms to estimate control-related process in the future.

In terms of modeling process, APC has always been focused on a data-driven approach, where models are built out of process data, either with dedicated step-tests or via a careful selection of historical data. This provides significant benefit in terms of engineering effort compared to model development considering first principles and equipment data.

The basic concept behind the APC technology is to use Model Predictive Control (MPC) as control synthesis technology, representing the plant and process units under consideration as a dynamic system, reacting according to continuous dynamics. This technology allows to map system response to known changes in variables, like setpoints, normally handled by plant personnel, to key variables in the process that are linked to production quality, production load and key constraints. This mapping is performed to the extent of identifying a dynamic model, linking the first variables, known as independent variables or inputs, to the latter ones, known as dependent or output variables.

ABB Model Predictive Control software, named Predict & Control, uses a modern and, at the same time, a very robust technology, based on state-space formulation and use of an explicit state estimation via a Predictor based on Kalman filter (Figure 4).

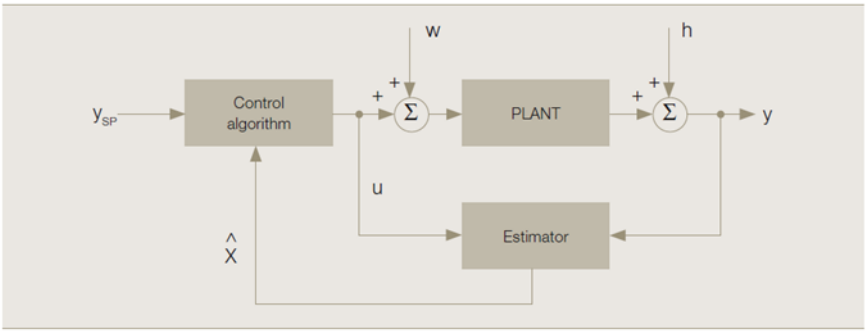

Figure 4: Basic principle of ABB's Predict & Control.

3.3 Plant Performance Optimization

The quantifiable process benefits achieved with this technology are often exceeded as a result of the addition of process expertise from APC application engineers and of the interaction between these engineers and the Clients specialists. These benefits will include reduced energy consumption, improved quality control, and increased throughput.

In addition to that, MPC delivers further benefits that are tangible but whose value is difficult to quantify, such as process stabilization and reduction in variability due personnel experience and operation style.

Illustration on how the MPC improve performance and moving operation to new optimized point are shown in Figure 5 below.

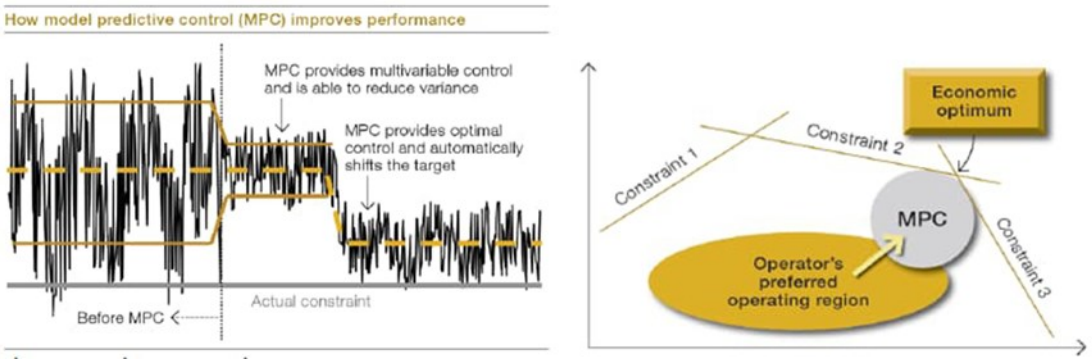

Figure 5: Illustration of MPC impact on variance and moving operation to optimized point.

An additional control layer (as Real-Time Optimization module) may be needed in cases where the economics of the process units or plant are complex and can change significantly over time.

In geothermal plant with steam network, the optimizer covers balancing steam over the various steam sources so to minimize production costs and calculating the optimal load allocation for the relevant equipment by considering actual steam production, equipment efficiency curves, equipment limits and relevant constraints, and transfer lines losses.

The optimizer then dispatches these orders to an APC control layer, which provides coordinated, decoupled control of pressure and power generation, which will stabilize steam headers and steam transfer lines, implement optimal load allocation and resulting steam transfer as computed by the Real Time Optimizer, and reject disturbances, balance variability in the steam production.

The base control level modulates the actuators affecting the plant to maintain the measured process quantities at their setpoints (see Figure 6).

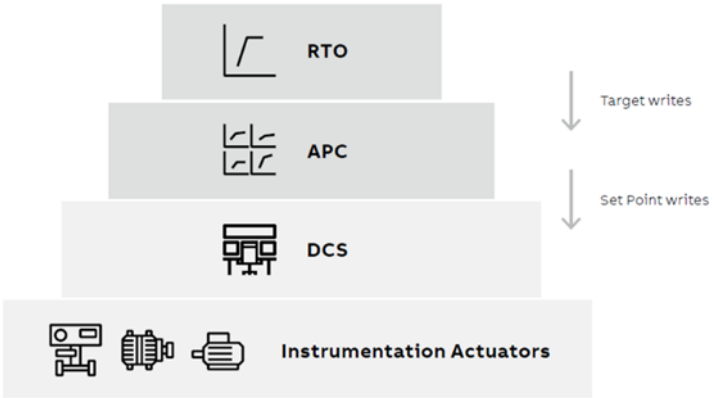

Figure 6: Real-Time Optimizer and Advanced Process Control integrated solution.

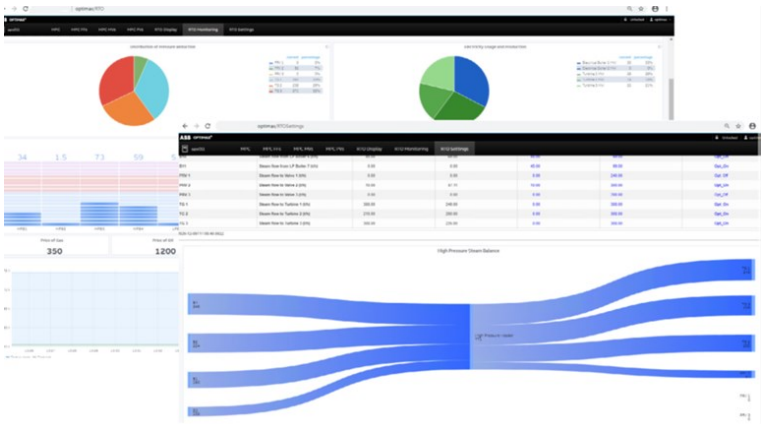

Figure 7: Sample of advanced dashboards providing insights on Steam Network economics and efficiency.

Steam & Power Optimization has a very modular, scalable software configuration based on ABB OPTIMAX and Predict & Control multivariable controller software. The same architecture and same software modules can be applied to small and very large steam networks, including the ones in geothermal power plants. Sample of advanced dashboards providing insights on Steam Network economics and efficiency is shown in Figure 7.

4. SECURING CYBER THROUGH ABB ABILITY™ CYBER SECURITY WORKPLACE (CSWP)

One key part of whole digital transformation ecosystem is the exchange of data internally as well externally and to ensure the data transfer is safe and secure, where the relevant Cyber Security practices must be in place. ABB's Cyber Security Workplace (CSWP) addresses the cybersecurity aspects of OT/IT convergence, ensuring secure integration. This comprehensive software ecosystem enhances the reliability, efficiency, and intelligence of geothermal facilities.

4.1 Cyber Security

Cyber-attacks against industrial plants are growing in frequency, level of sophistication, and degree of harm inflicted. Today's advanced threats need advanced cyber security solutions designed for industrial users protecting your systems without compromising reliability. Staying ahead of cyber criminals and keeping your production secure requires a new simplified approach to managing foundational security.

The situation of where the cyber disaster in the industrial plant is typical. Thousands of distributed assets, multiple control loops, hundreds of controllers, and next to no cyber security.

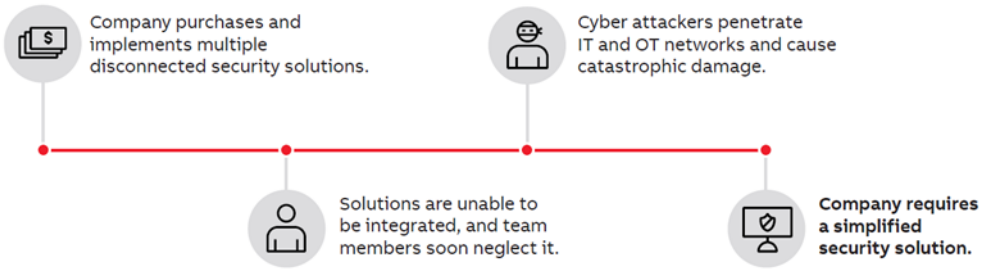

Figure 8: Typical sequence of events of cyber-attack.

A common misconception is that both cyber-attacks and cyber security controls are sophisticated and complex. In fact, the methods criminals use to infiltrate industrial networks are often relatively straightforward. When cyber security controls are perceived to be complex or intimidating to operate and manage, one of two things happens:

1. Implemented security controls get neglected, significantly reducing their efficiency.
2. Security is viewed as a hassle and is never implemented.

A customer's investment in security controls is wasted if those tools are not implemented, operated, and maintained correctly.

4.2 ABB Ability™ Cyber Security Workplace (CSWP)

ABB Ability™ Cyber Security Workplace automates security insights and defense. It gives security teams complete visibility of their security controls by providing a consolidated view of all security controls in a simple and intuitive user interface.

ABB Ability™ Cyber Security Workplace collects security-relevant data from ABB and third-party cyber security solutions and forwards it into a consolidated native application. Operators can seamlessly monitor the status of their security controls, perform maintenance activities to increase resiliency, and receive alerts with actionable insights to remediate threats and reduce risks.

As one simplified platform for security operations, the solution will shift from multiple siloed security tools and take charge of your security program. It will manage security updates, malware protection, and system backups, provide set alarms and get notified when increased risk exists, provide risk root cause analysis and remediation playbooks to identify and neutralize risks, manage remote access by setting remote access time limits, temporary passwords, and audit history tracking, and provide configurable reports to quickly show compliance.

ABB Ability™ Cyber Security Workplace was designed to quickly identify increased risk in your control system environment, such as with checkmarks to signify there are no cases of increased security risk, stop-light like KPIs to identify and prioritize risks, or intuitive actions to remediate risk, e.g., start a backup job when a backup fails.

When a cyber threat is present in the IT network, it may be best to isolate systems from the network to protect critical systems to prevent production loss or harm to personnel. Cyber Security Workplace enables system

administrators to isolate the control system network at the click of a button to keep critical assets safe and production online.

In addition, ABB Ability Cyber Security Workplace's risk root cause analysis was built to provide the cyber expertise by identifying the node(s) and reason that increased risk exists, detailing the potential impact of the risk, as well as providing remediation steps to return risk to an acceptable level.

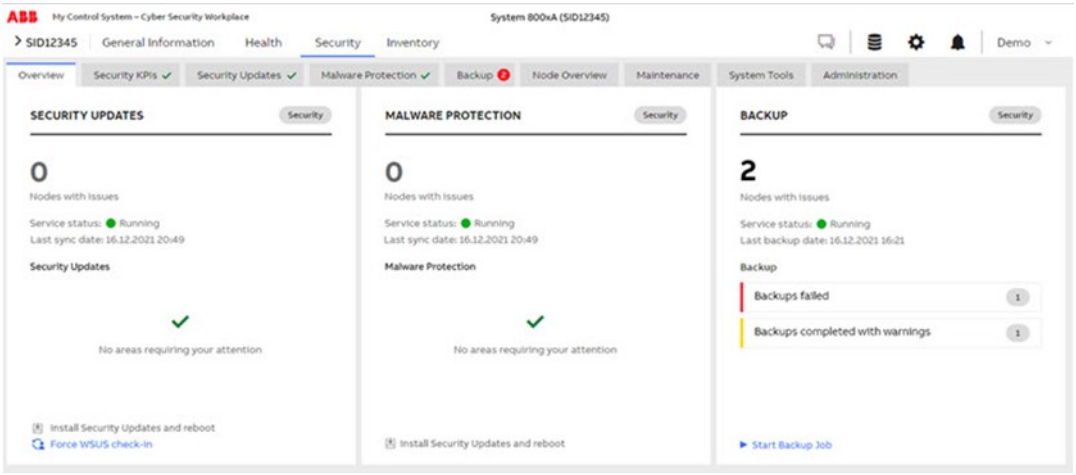

Figure 9: Sample of ABB Cyber Security Workplace dashboard providing simple and intuitive user interface.

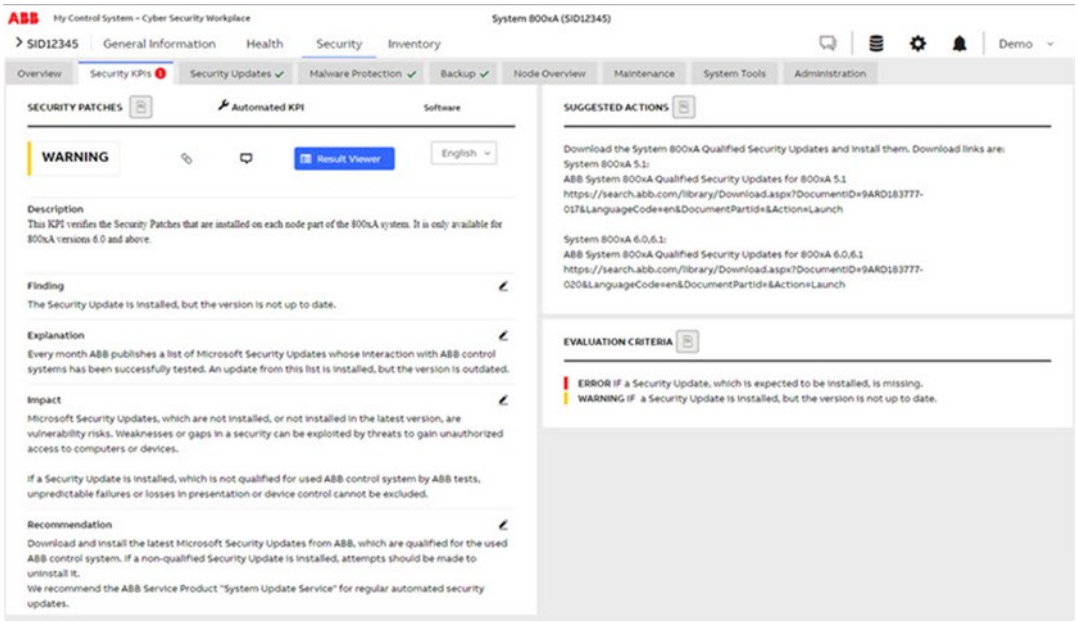

Figure 10: Sample of Risk Root Cause analysis dashboard.

4.3 The implementation

ABB Ability™ Cyber Security Workplace connects to implemented security controls, such as Microsoft WSUS or McAfee ePO, to gather pertinent information about the performance and status of those controls. The collected data is transformed to easy-to-understand KPIs and presented to the user. The user can also interact with some of the controls to perform basic cyber security related tasks e.g. reboot a node.

The workplace fits into the Reference Architecture and can be integrated with the control systems and security controls of ABB Ability™ System 800xA, ABB Ability™ Symphony Plus; and Microsoft WSUS, McAfee ePO, Symantec SEPM, Acronis Backup, and Quest Netvault.

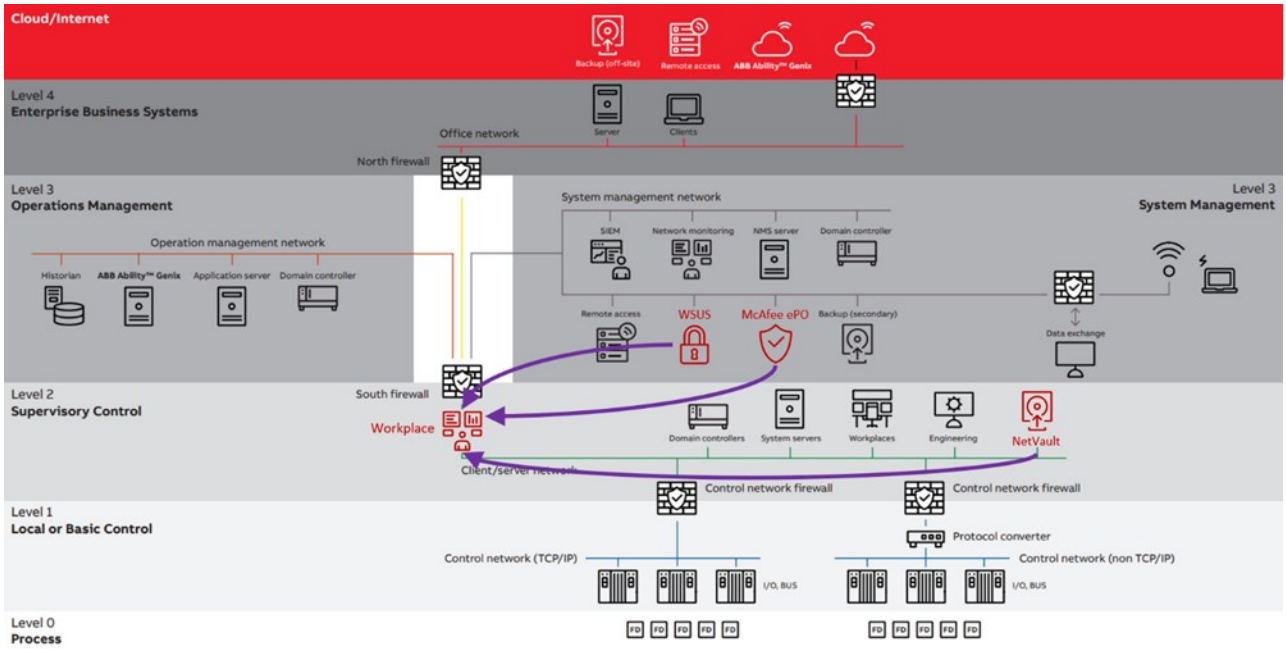

Figure 11: Typical implementation of ABB Cyber Security Workplace.

5. CONCLUSION

As a technology leader in electrification and automation, ABB is at the core of propelling the energy transition forward. This includes the ABB digital solutions with its range of solutions that optimizes asset operation and maintenance, power consumption and processes, as wells cyber security of the system. This is crucial for stabilizing renewables and effective data management provides transparency and actionable insights, driving efficiency and sustainability gains, including in geothermal power segment.

Keywords: Geothermal Dryhouse, Coffee Drying, Sustainable Energy, Heat Transfer,Economic Benefits

ABSTRACT

The coffee farmers in Kamojang currently rely on conventional sun-drying methods, facing challenges due to the area's cold ambient temperatures and unpredictable weather. To address this, PT PGE Area Kamojang constructed a geothermal dry house utilizing a heating pipe connected to an existing geothermal steam pipeline. In this comprehensive study, the existing geothermal dry house undergoes evaluation from both technical and business perspectives. The technical assessment focuses on the thermal performance of the heating pipe, determining the heating load, required pipe length, and the impact of pipe operation on dry house temperature. Analytical methods reveal a required heating load of 10.94 kW, necessitating a 41.79 m pipe length. Subsequently, experimental trials conducted on multiple occasions show enhancements through technical adjustments, such as steam trap installation and valve rearrangement, resulting in improved heating pipe performance, maintaining temperatures above 40°C for extended periods.

On the business front, qualitative analysis examines the potential for profit enhancement stemming from reduced drying durations. By substituting conventional methods with the geothermal dry house, drying times could potentially decrease from 2-3 weeks to 1-2 weeks, while preserving coffee flavour and minimizing odor issues. The business evaluation anticipates significant benefits for farmers, correlating shorter drying times with increased profitability. This integrated approach, blending technical optimization with business insights, underscores the promising solution offered by the geothermal dry house, addressing operational challenges and driving economic gains for coffee farmers in Kamojang.

1. INTRODUCTION

Indonesia has a geothermal energy potential of 23.9 GW of which only 10% of the geothermal potential is utilized (Ayuningtyas et al., 2021). The utilization of geothermal potential can be divided into two methods, namely direct and indirect utilizations (Lukmana & Helmy, 2020). The main example of indirect utilization is for electricity generation. Meanwhile, examples of direct use are hot water baths, room heaters, and dryers for plantation and fishery products. However, currently the use of geothermal energy in Indonesia is still dominated by indirect use for electricity generation (Darma et al., 2021).

Kamojang is a region in Bandung Regency, West Java, Indonesia, area which produces a primary plantation commodity, namely Arabica coffee (Coffea arabica L.). According to the local coffee farmers, the production rate of Kamojang coffee green beans usually reaches 8-9 tons per year. The optimal temperatures for coffee drying are in the range of 35-45°C (da Costa et al., 2021). However, currently Kamojang coffee farmers still rely on natural drying using the sun's radiation. The frequently changing weather and low temperatures in the Kamojang region make coffee drying take 2-3 weeks. Therefore, PT Pertamina Geothermal Energy (PGE) Area Kamojang, through the Corporate Social Responsibility (CSR) scheme, took the initiative to create a geothermal steam-powered coffee dryer machine named Geothermal Coffee in 2018 with the hope that coffee drying will no longer depend on weather and climate so that drying can be done more efficiently. However, (Badan Perencanaan Pembangunan Daerah Kabupaten Bandung, 2021) stated that this method was not optimal because coffee has a sensitivity to absorb the smell of sulfur from geothermal steam, which affects the taste of coffee and the large number of coffee beans that are damaged due to overly high temperatures. Responding to this, PT PGE Area Kamojang is looking for an alternative method of drying coffee, namely using a dryhouse. Currently, PT PGE Area Kamojang has built a trial dryhouse with heating pipes which is connected to blowdown on the main pipeline that distributes geothermal steam to the Kamojang Geothermal Power Plant (GPP). Geothermal dryhouse has the advantages of being weather independent, available heat around the clock, and naturally-controlled temperature and humidity. This method is similar to conventional drying method but relying on geothermal as a constant heat supply instead

of the fluctuative sun radiation. Moreover, the existing dryhouse has been improved to mitigate sulfur smell issues by using double door access and a distant steam exhaust.

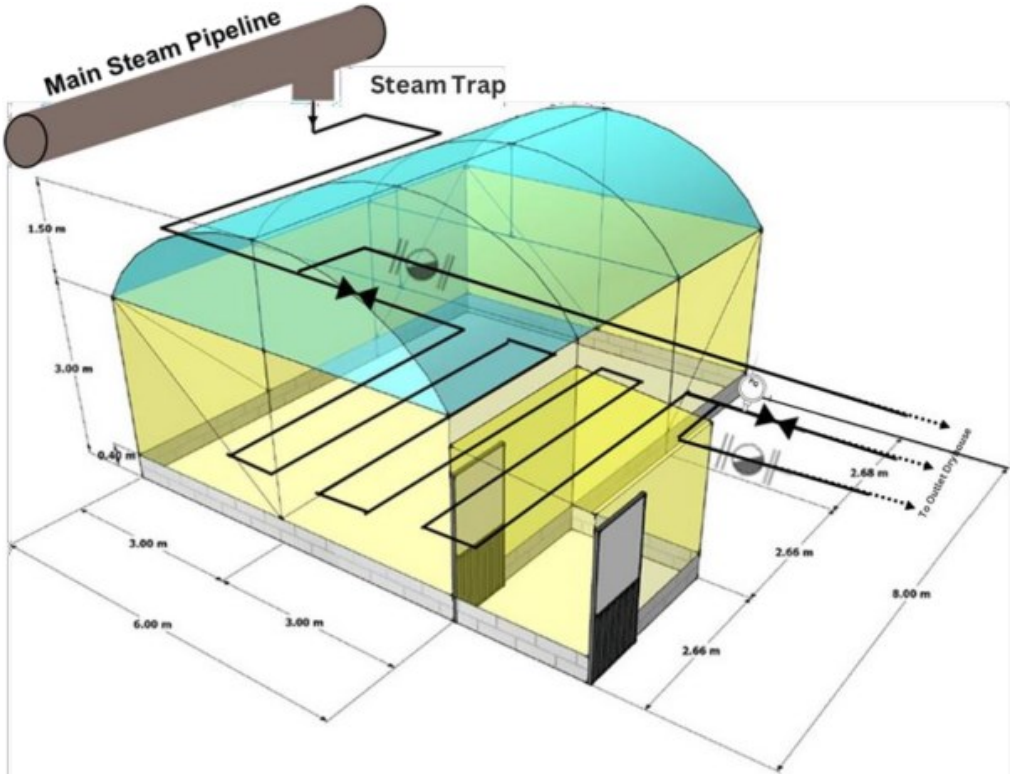

Figure 1: Geothermal Dry House Design.

Figure 2: Geothermal Dry House Construction.

2. GEOTHERMAL DRYHOUSE DESIGN

The existing geothermal dryhouse has a width of 6 m, length of 8 m, and height of 4.5 m, as shown in Figure 1. The heating pipe utilizes the blowdown from the main pipeline as the heat source so that the geothermal steam flows from the blowdown towards the dryhouse to transfer its heat to the dryhouse air. The total length of the existing heating pipe is 43.5 m.

3. METHODOLOGY

3.1 Technical Section

The technical evaluation studies the thermal performance of the heating pipe to calculate the dryhouse heating load, the required heating pipe length, the effect of heating pipe operation on the dryhouse temperature, and the suggested technical improvements. The technical evaluation is performed through analytical and experimental methods explained in the following.

3.1.1 Analytical Method

The analytical method is used to evaluate the dry house technically based on the necessary governing equations. In order to maintain the dry house temperature at a desired value, the heating load must be equal to the rate of heat loss and the rate of trapped radiation. The energy balance equation of dry house is expressed in Equations (1) and (2) as follows:

$$Q_{load} = Q_{loss} - Q_{rad} \quad (1)$$

$$Q_{loss} = (Q_{str} + Q_{air}) \cdot C_{cond} \cdot C_{cli} \quad (2)$$

where Q_{load}, Q_{loss}, Q_{str}, Q_{inf}, Q_{rad}, C_{con}, C_{cli}, and are heating load, structural heat loss rate (kW), heat loss rate through air infiltration (kW), heat gain through trapped radiation (kW), construction factor, and climate factor, respectively. The structural heatloss rate is calculated using Equation (3) as follows:

$$Q_{str} = U \cdot A \cdot (T_{\infty,dh} - T_{\infty,amb}) \quad (3)$$

where U, A, $T_{\infty,dh}$, and $T_{\infty,amb}$ are structural overall heat transfer coefficient (kW/m2·K), wall and roof area (m^2), dry house temperature (°C), and ambient temperature (°C) respectively. The heat loss rate through air infiltration is calculated using Equation (4) as follows:

$$Q_{air} = N \cdot V_{dh} \cdot \rho_{a,dh} \cdot c_{pa,dh} \cdot (T_{\infty,dh} - T_{\infty,amb}) \quad (4)$$

where N, V_{dh}, $\rho_{a,dh}$, $c_{p,a,dh}$, $T_{\infty,dh}$, and $T_{\infty,amb}$ are air exchange rate (s^{-1}), dry house inner volume (m^3), density of air inside dry house (kg/m^3), isobaric specific heat of air inside dry house (kJ/kg·K), dry house temperature (°C), and ambient temperature (°C) respectively.

$$Q_{rad} = F \cdot (A_{dh} I_h + A_{roof} I_{dn}) \quad (5)$$

where F, A_{dh}, A_{roof}, I_h, and I_{dn} are fraction of trapped radiation energy (%), wall and roof area (m^2), roof area (m^2), horizontal irradiation intensity (kW/m^2), and direct normal irradiation intensity (kW/m^2), respectively.

The geothermal steam flows inside the heating pipe and transfer its heat to the dry house air. This involves convection heat transfer on the inner and outer pipe walls, conduction heat transfer at the pipe wall, and radiation heat transfer on the outer pipe walls. The thermal circuit of the heat transfer process is shown in Figure 3.

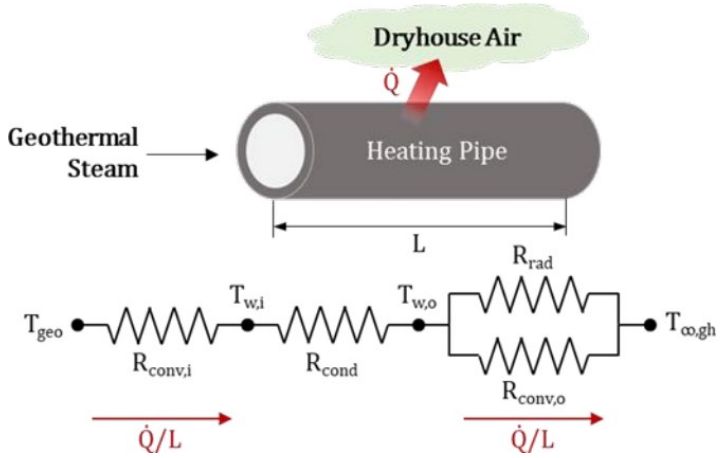

Figure 3: Thermal resistance of heat transfer from geothermal steam to dry house air.

The geothermal steam flowing inside the heating pipe is at saturated vapor phase. Therefore, film condensation occurs as the steam transfers heat to the dry house air. The forced convection heat transfer coefficient and thermal resistance with film condensation for internal flow inside a horizontal cylindrical pipe are expressed in Equations (6) and (7), respectively, according to Bergman et al. (2017) and Berian and Khusaini (2022) as follows:

$$h_{conv,i} = 0.555\left[\frac{g\rho_l(\rho_l-\rho_v)k_l^3}{\mu_l(T_{sat}-T_{w,i})D_i}\left(h_{fg}+\frac{3}{8}c_{p,l}(T_{sat}-T_{w,i})\right)\right]^{0,25} \quad (6)$$

$$R_{conv,i} = \frac{1}{h_{conv,i}\,\pi D_i\,L} \quad (7)$$

where $h_{conv,i}$, $R_{conv,i}$, g, ρ_l, ρ_v, k_l, μ_l, D_i, L, h_{fg}, $c_{p,l}$, T_{sat}, and $T_{w,i}$ are convection heat transfer coefficient on inner pipe wall (kW/m^2·K), convection thermal resistance on inner pipe wall (m·K/kW), gravitational acceleration (m/s^2), condensate density (kg/m^3), steam density (kg/m^3), condensate thermal conductivity (kW/m·K), condensate viscosity (Pa·s), inner pipe diameter (m), pipe length (m), condensate isobaric specific heat (kJ/kg·K), saturation temperature (°C), and inner pipe wall temperature (°C), respectively.

The outer pipe wall is exposed to the dry house air flowing across the pipe. The natural convection heat transfer coefficient and thermal resistance of external flow across a cylindrical pipe are expressed in Equations (8) and (9), respectively, according to Bergman et al. (2017) and Berian and Khusaini (2022) as follows:

$$h_{conv,o} = \frac{k_f}{D_o}\left[0{,}6+\frac{0{,}387Ra_D^{\frac{1}{6}}}{\left[1+\left(\frac{0{,}559}{Pr}\right)^{\frac{9}{16}}\right]^{\frac{8}{27}}}\right]^2 \quad (8)$$

$$R_{conv,o} = \frac{1}{h_{conv,o}\pi D_o L} \quad (9)$$

where $h_{conv,o}$, $R_{conv,i}$, k_f, Ra_D, Pr, D_i, and L are convection heat transfer coefficient on outer pipe wall (kW/m^2·K), convection thermal resistance on outer pipe wall (m·K/kW), fluid thermal conductivity (kW/m·K), Rayleigh number, Prandtl number, outer pipe diameter (m), and pipe length (m), respectively.

The heating pipe also emits radiation to the surrounding. The radiation heat transfer coefficient and thermal resistance are expressed in Equations (10) and (11), respectively, as follows:

$$h_{rad} = \sigma\epsilon\left(T_{w,0}^2+T_\infty^2\right)\left(T_{w,o}-T_{\infty,dh}\right) \quad (10)$$

$$R_{rad} = \frac{1}{h_{rad}\,A_{w,o}} \quad (11)$$

where h_{rad}, R_{rad}, σ, ϵ, $A_{w,o}$, $T_{w,o}$, and T_∞ are radiation heat transfer coefficient (kW/m^2·K), radiation thermal resistance (m·K/kW), emissivity, Stefan-Boltzmann constant, outer pipe wall area (m^2), outer pipe wall temperature (K), and dryhouse temperature (K), respectively.

The values of the parameters needed in the analytical heat transfer calculations in heating pipes are obtained through field data and assumptions using literature studies as shown in Table 1.

3.1.2 Experimental Methode

The heating pipe is operated by opening the blowdown valve hence the geothermal steam from the main pipeline could flow inside the heating pipe towards the dryhouse. Meanwhile, the outlet valve at the end of the heating pipe remains closed. During the pipe operational, the dryhouse temperature is measured using a thermohygrometer. Therefore, the dryhouse air temperature during the heating pipe operation could be evaluated. After minimum 24 hours of operation, the blowdown valve is closed again to shut down the heating pipe.

Geothermal Dry House has the advantages of being weather-independent, available heat around the clock, and naturally-controlled temperature and humidity. Based on technical evaluation the results indicated that the heating pipe was able to increase the dry house temperature. However, the condensate builds up inside the heating pipe reduces the dry house temperature minutes after the heating pipe operation. Therefore, it is responded by installing two stream traps, each installed at the inlet and outlet of the drying house to reduce condensate in the steam entering the drying house and remove the condensate formed while the steam is in the drying house.

Table 1: Values of parameters in the analytical calculations.

Parameter	Value	Source
Geothermal steam mass flow rate	0.114 kg/s	Field data
Geothermal steam temperature	187.2°C	Field data
Geothermal steam pressure	11.8 bara	Field data
Geothermal steam phase	Saturated vapor	Field data
Heating pipe segment length inside dry house	43.5 m	Field data

Parameter	Value	Source
Dry house inner volume	200.55 m^3	Field data
Dry house wall and roof area	156.27 m^2	Field data
Dry house wall area	55.64 m^2	Field data
Average daily dry house temp. without heater	36.8°C	Field data
Dryhouse design temperature	40°C	Interview with local farmer; da Costa (2021)
Ambient temperature	19°C	Rudiyanto et al. (2022)
Ambient pressure	0.85 bara	Rudiyanto et al. (2022)
Dry house overall heat transfer coefficient	0.5 kW/m²·K	ASHRAE (2019)
Air exchange rate due to infiltration	0.0004167/s	ASHRAE (2019)
Fraction of trapped radiation	75%	Ahamed et al. (2018)
Horizontal irradiation intensity	0.00122 kW/m²	Solargis (2019)
Direct normal irradiation intensity	0.001277 kW/m²	Solargis (2019)
Construction factor	1.02	ASHRAE (2019)
Climate factor	0.41	ASHRAE (2019)
Heating pipe thermal conductivity	0.0567 kW/m·K	

3.2 Operation Hours (Day/Month/Year) & Maintanance Scheme (In-House, Contracted Out Service, Government, Others

3.2.1 Operation Hours (Day/Month/Year)

The actual operation hours for geothermal dry house entail a continuous cycle of work, with operations spanning 24 hours each day. This setup results in a substantial cumulative working time of 5,760 hours annually.

Actual operation hours:
Working hours 24 hours per day
Working days 240 days per year
Total working hours 5,760 hours per year

3.2.2 Maintanance Scheme (In-House, Contracted Out Service, Government, Others)

The Geothermal Dry House conducts proactive and preventive maintenance with regular schedules to avoid production failures. These plans are maintained based on manual machine operation data, predictive maintenance principles, and machine degradation level analysis. In line with the concept of sustainable power plant operations, socio-ecological safety is ensured through social inclusion practices in the Geothermal Coffee Process program, and monitored through annual Social License Index (for social safety) and annual geophysical surveys (for steam resource sustainability).

3.2.3 Other Maintanance Measures (Training, After-Sales Service)

In the realm of geothermal coffee processing, additional maintenance measures are essential for seamless operations and maximizing technology efficiency.

1. Regular Training Programs

Figure 4: Coffee Training for Community.

Training programs are essential not only for personnel involved in operating and maintaining complex machinery but also for coffee farmers. These programs equip farmers with the knowledge and skills needed to effectively manage their coffee farms in conjunction with geothermal technology. Additionally, operators and technicians receive training on the operation, maintenance, and troubleshooting of geothermal coffee processing equipment.

2. Preventive Maintenance Plans
   Developing and implementing preventive maintenance plans for Canaya Geothermal Dry house, including regular inspections, cleaning, calibrations of machinery to prevent potential breakdowns and extend the lifespan of the dry house.
3. Scheduled Monitoring Systems
   Scheduled monitoring systems in Canaya Geothermal Dry house ensure ideal conditions for drying coffee beans by continuously tracking temperature and humidity levels. This critical oversight maintains quality and enhances efficiency.

3.3 Bussiness Section

This project was 100% fully funded by PT. Pertamina Geothemal Energy Tbk – Area Kamojang. The CSR scheme provides financial support for capital expenditure needs and working capital requirements.

The market potential for geothermal dry house technology within the next 5 years in the coffee industry appears promising. The efficiency, quality assurance, and extended drying capabilities through expansion of the geothermal dry house can attract more coffee farmers and buyers, leading to potential growth and market expansion:

1. Increased Efficiency: The geothermal dry house can accelerate drying time significantly, up to 75% faster than conventional methods. This increased efficiency can lead to higher productivity and throughput in coffee drying processes.
2. Extended Drying Season: The ability to dry coffee beans regardless of the season can provide a competitive advantage to coffee farmers, allowing them to operate year-round and be less affected by seasonal variations. This extended drying season could attract more farmers to adopt this technology.
3. Stable Drying Conditions: The stability of drying temperature and humidity in geothermal dry houses can help maintain the quality of coffee beans, ensuring that the flavor is not compromised. This quality assurance can be a crucial selling point in the market.
4. Contamination Reduction: By reducing the risk of contamination from dust, dirt, and insects, the geothermal dry house method ensures higher-quality coffee beans. This assurance of quality can be a key factor in attracting buyers who prioritize cleanliness and quality standards.
5. Consumer Preference: The positive testimonies from local coffee farmers regarding the taste and absence of smell issues in the dried coffee could lead to increased consumer trust and preference for dried coffee using geothermal technology.

With its array of advantages, geothermal dry house technology presents promising potential for significant market growth and expansion in the coffee industry over the next five years. By enhancing efficiency, extending drying seasons, ensuring stable drying conditions, reducing contamination risks, and garnering increased consumer preference, this technology opens new for coffee farmers and stakeholders across the coffee supply chain to optimize quality and productivity, while expanding their market share.

As for the calculation for forecasting the market size for geothermal dry house technology in the coffee industry in Indonesia over the next 5 years based on value creation by 2023:

Table 2: Value Creation by 2023.

No.	Description	Value
1	Revenue of Geothermal Coffee Management	Rp. 182.613.999
2	Cost saving of geothermal coffee process	Rp. 36.855.632
	Total Real of Value Creation by 2023	Rp. 182.613.999

Value Creation in 2023 : Rp. 182.613.999 Production per Month in 2023 : 2 tons Value Creation per Ton :

Value Creation per Ton = Value Creation / Production per Month (12)
= Rp. 182.613.999 / 2 tons
= Rp. 91.306.999 per ton

Production Growth = 5% per year (assumed) Projected Annual Value Creation:

Projected Annual Value Creation :

Table 3: Projected Annual Value Creation (per ton).

2024	2025	2026	2027	2028
Rp. 95,872,349	Rp 100,665,967	Rp 105,699,266	Rp 111,000,230	Rp 116,598,242

These calculations show the expected yearly value created by the geothermal dry house technology in the coffee industry from 2024 to 2028. Each year, the value created per ton of coffee is determined by multiplying the previous year's value by a 5% growth rate. This could estimate of how much value the technology is likely to generate annually over the five-year period.

Projected Market Size:
Multiply the value creation per ton by the total annual coffee production
Year 2024: Rp. 95,872,349 per ton * (production per month * 4 months)
= Rp. 95,872,349 per ton * (2 tons * 4 months)
= Rp. 95,872,349 per ton * 8
= Rp. 766,978,792

Table 4: Projected Market Size.

2024	2025	2026	2027	2028
Rp. 766,978,792	Rp. 1,207,991604	Rp. 1,691,188,256	Rp. 2,220,004,600	Rp. 2,798,357,808

*estimated increase of 1 ton in production per year compared to the previous year.

This calculation shows the market size for geothermal dry house technology in Indonesia's coffee industry by multiplying the value created per ton with total annual coffee production. It gives an idea of the market opportunity for this technology.

3.4 Resources

3.4.1 Local Manufacturing/Content of System

The equipment and machines of Canaya Geothermal Dry house were realized by PT. Pertamina Geothermal Energy Tbk in collaboration with local groups.

Table 5: Equipment & Service Project Items.

No.	Equipment & Service Project Items	% (Est. Cost Invesment)	Local Community Involvement
1	Outer pipe wall	15%	provided by local/domestic suppliers
2	Steam trap dry house	20%	provided by local/domestic suppliers
3	Dry house construction	30%	Local labour in technical and general skill in collaboration with PGE team
4	Construction and Modification	35%	Local labour in technical and general skill in collaboration with PGE team

3.4.2 Local Service Content

- Raw material: 100% has been supplied from within 50 kilometres from the power plant, with 70% coming form local industries or farmers and 30% coming from the shareholders
- Spare Parts and Services: 100% of spare parts and services are supplied or provided by local/domestic manufacturers or suppliers (within Indonesia region), thus the maintenance/service costs are low, as well as emergency shutdowns
- The workforce comes from within the company in collaboration with local workers with appropriate competencies and skills

4. RESULT AND DISCUSSION

4.1 Technical Evaluation : Analytical Method

Based on the calculation results, the total heat loss in the dryhouse is 11.14 kW involving the construction factor coefficient and climate factor coefficient of 1.02 and 0.41 respectively. Most of the heat losses occur through the structure of the dryhouse walls and roof as much as 9.35 kW. Meanwhile, the rest was caused by air infiltration of 1.79 kW. Since the dryhouse obtains heat through trapped radiation of 0.2 kW, the heating power required to keep the dryhouse air temperature constant is 10.94 kW, as shown in Table 6 .

Table 6: Geothermal dryhouse heat loss and heat load.

Parameter	Value	Unit
Structural heat loss	9.35	kW
Air infiltration heat loss	1.79	kW
Construction factor	1.02	-
Climate factor	0.41	-
Total heat loss	11.41	kW
Radiation heat gain	0.2	kW
Heat load	10.94	kW

The convection heat transfer coefficient with film condensation on the inner wall of the pipe is 27 kW/m2·K. Convection heat transfer involving a phase change has a higher heat transfer coefficient than convection without a phase change. The total thermal resistance from convection, conduction and radiation is 561.26 m·K/kW. Thus, the heat transfer rate per unit pipe length is 0.2618 kW/m and the required length of heating pipe to meet the heating power requirement (10.94 kW) is 41.79 m, as shown in Table 7. Therefore, the existing pipe length (43.5 m) has met the required pipe length.

Table 7: Results of analytical heating pipe heat transfer calculation.

Parameter	Value	Unit
Convection heat transfer coeff. on the inner pipe wall	27.0	kW/m^2·K
Convection heat transfer coeff. on the outer pipe wall	0.0075	kW/m^2·K
Radiation heat transfer coefficient	0.0095	kW/m^2·K
Convection thermal resistance on the inner pipe wall	0.44	m·K/kW
Pipe wall conduction thermal resistance	0.63	m·K/kW
Convection thermal resistance on the outer pipe wall	0.0013	m·K/kW
Radiation thermal resistance	1,004.1	m·K/kW
Total thermal resistance	561.26	m·K/kW
Inner pipe wall temperature	186.99	^{o}C
Outer pipe wall temperature	186.72	^{o}C
Heat transfer rate per unit length	0.2618	kW/m
Required heating pipe length	41.79	m

Since the geothermal steam is in the saturated vapor phase when it enters the inlet of the dryhouse, the heat transfer from the steam to the air of the dryhouse causes the formation of condensate from the steam. Based on the results of the calculation of the heat transfer parameters in Table 2, the rate of condensate formation per unit pipe length is 0.000235 kg/s·m or 0.8462 L/h·m. With an existing pipe length of 43.5 m, the total condensate formation rate is 0.010224 kg/s or 36.81 L/h, as shown in Table 8.

Table 8: Results of condensatiozszn rate calculation.

Parameter	Value	Unit
Saturation temp. at the geothermal steam pressure	187.2	^{o}C
Existing heating pipe length	43.5	m
Condensation rate per unit length	0.000235	kg/s·m
	0.8462	L/h·m
Total condensation rate	0.010224	kg/s
	36.81	L/h

4.2 Experimental Method: First Trial (16-18 January 2023)

The trial operation of the heating pipe was performed twice. The first trial was on 16-18 January 2023, while the second trial was on 27 April – 4 May 2023. During the first trial, the blowdown valve from the main pipeline was opened on 16 January 2023 at 02:00 p.m. The valve at the end of the heating pipe at the outlet of the dryhouse remains closed. The dryhouse temperature profile after heating pipe operation on Trial 1 is shown in Figure 4. The initial dryhouse temperature when the blowdown valve was opened was 33°C. After the blowdown valve was opened, the dryhouse temperature gradually increased until reaching the maximum temperature of 36.5^{o}C was achieved 28 minutes after operation started (at 02.28 p.m.). Afterwards, the dryhouse temperature showed a declining trend. Therefore, the heating pipe could not reach the dryhouse design temperature of 40°C. During the night, the dryhouse temperature declined to as low as 23°C before increasing again in the morning. The failure to

reach the design temperature was caused by the condensate buildup in the heating pipe which cannot be removed because the end valve is closed. With an inner heating pipe diameter of 0.02664 m and a length of existing heating pipe of 43.5 m, the volume of the cavity in the heating pipe is 0.024 m^3 or 24 L. If the rate of condensate formation based on Table 3 is 36.81 L/h, then the condensate will fill all the cavities in the pipe within 40 minutes after the heating pipe is operated.

Based on the evaluated results of the first trial, three technical improvements are suggested:

1. Two steam traps are needed, each installed at the inlet and outlet of the dryhouse. The steam trap at the inlet reduces condensate in geothermal steam that flows into the dryhouse. Meanwhile, the steam trap at the outlet removes the condensate that forms while the steam is in the dryhouse. Based on the results of calculating the rate of formation of condensate in Table 4 of 0.03681 tph and by providing an allowance factor of 50%, the required capacity of each steam trap is 0.055 tph of condensate.
2. The geothermal steam will experience a pressure drop when flowing in the heating pipe. While the steam pressure at the main pipeline blowdown can be known from the operational data of Kamojang GPP, a pressure gage should be installed at the dryhouse outlet to calculate the pressure drop experienced by the steam inside the heating pipe.
3. Before the heating pipe enters the drying house, there is a 15 meter-long heating pipe segment between the main pipeline blowdown and the drying house inlet. To reduce heat loss in this pipe segment and maximize the heat transferred to the dryhouse, this heating pipe segment should be insulated.

4.3 Experimental Method: Second Trial (27 April – 4 May 2023)

In response to the suggested technical improvements based on the first trial, two steam traps, a pressure gauge, thermal insulation were installed before the second trial. During the second trial, the blowdown valve from the main pipeline was opened on 27 April 2023 at 09:00 a.m. The dryhouse temperature profile after heating pipe operation on Trial 2 is shown in Figure 4. The initial dryhouse temperature when the blowdown valve was opened was 39°C. After the blowdown valve was opened, the dryhouse temperature gradually increased until surpassing the dryhouse design temperature of 40°C at 09:03 a.m. The dryhouse temperature kept increasing until reaching the maximum temperature of 43°C at 10:42 a.m. (1 hour and 42 minutes after heating pipe operation). The dryhouse temperature remained higher than 40°C until 11:19 a.m. and then was followed by a declining trend with a slight increase between 00:44 p.m. and 01:27 p.m. On Trial 2, the dryhouse temperature during the night was maintained higher than on Trial 1. This indicates that the technical improvements managed to improve the heating pipe's performance on maintaining the dryhouse temperature. However, the presence of condensate buildup inside the heating pipe suggests that the newly installed steam traps did not work properly.

Based on the evaluated results of the second trial, two technical improvements are suggested:

1. To discover why the condensate buildup still occurred, recheck the newly installed steam traps by exchanging the inlet and outlet steam traps.
2. To improve the air circulation and minimize the sulfur's smell, two access doors and distant air exhaust should be added into the dryhouse.

4.4 Experimental Method: Third Trial (31 May – 5 June 2023)

In response to the suggested technical improvements based on the second trial, the inlet and outlet steam traps' were exchanged to discover whether the condensate buildup issue was caused by the steam traps themselves or by a systemic issue. During the second trial, the blowdown valve from the main pipeline was opened on 31 May 2023 at 11:00 a.m. The dryhouse temperature profile after heating pipe operation on Trial 3 is shown in Figure 5. The initial dryhouse temperature when the blowdown valve was opened was 39°C. After the blowdown valve was opened, the dryhouse temperature gradualy increased until surpassing the dryhouse design temperature of 40°C at 11:18 a.m. The dryhouse temperature kept increasing until reaching the maximum temperature of 43°C at 00:01 p.m (1 hour and 1 minute after heating pipe operation). The dryhouse temperature remained higher than 40°C until 02:39 p.m. and then was followed by a declining trend. On Trial 3, the dryhouse temperature during the night was maintained higher than on Trial 2. This indicates that the technical improvements managed to improve the heating pipe's performance on maintaining the dryhouse temperature.

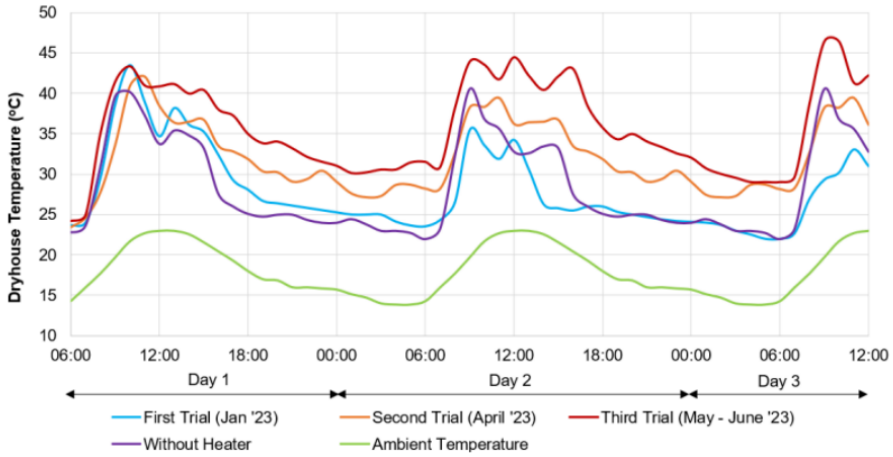

Figure 5: Dryhouse temperature after heating pipe operation from Trials 1, 2, and 3.

4.5 Business and Social Evaluation

4.5.1 Benefits (User, Community, Country)

Benefits to Project Owners (PT. Pertamina Geothermal Energy Tbk.)

- Direct-use of company's raw material to Corporate Social Responsibility Program
- Creates good image for the company and relevant shareholders

Benefits to the community and surrounding

- Helps in economic growth in the community by increasing revenue by around IDR 182.6 million Rupiah per year.
- Saves around IDR 36.8 million Rupiah per year in operational costs for local economic activities.
- Enhances the value of the local community through the originality of Kamojang's signature Canaya Geothermal Coffee
- Creates 35 partner B2B & B2C
- Contributes to organic waste recycling by up to 419.2 kg/year

Benefits to the Country

- Contributes to reduce greenhouse gas emission from using geothermal energy instead of fossil fuel for dry house approximately 21,949 tons CO2 per year.
- Promotes Kamojang's signature product, "The Canaya Geothermal Coffee" to the wider community, which can become a regional to international tourism attraction.

Figure 6: Canaya Geothermal Coffee.

4.5.2 Corporate Social Responsibility Program

The Geothermal Coffee Group, as one of PGE Kamojang's CSR programs, consists of a coalition of 3 coffee groups from Kamojang and its surroundings. This group aims to improve the welfare of local farmers by applying green processing principles in coffee processing. The members of the group are also often referred to as the Geothermal Coffee Process or GCP group, comprising 6 core members from Penyoe Kakopi, Ecovill, and the

Akkar Kamojang. This group utilizes geothermal dry house for drying coffee cherries, making it 75% more effective compared to sun drying. Initially, drying required a duration of 1 to 1.5 months, but with the geothermal dry house, drying can be accomplished in just 3-7 days. Additionally, group members can enhance their capacities based on their skills, whether as coffee farmers, processors, or baristas. Capacity building agendas and bootcamps are planned and partially realized to recruit outstanding talents that contribute to the sustainability of the Geothermal Coffee Group. At least 1,540 customers enjoy the GCP coffee products. Furthermore, the group strives to expand its business and market through both B2C and B2B models.

4.5.3 Community/People Awareness, Participation, and Acceptence

Through The Canaya Geothermal Coffee, local community awareness of coffee cultivation potential increases, and with the presence of The Canaya Geothermal Coffee, it also supports the following beneficiaries: 6 main managers of The Canaya Geothermal Coffee, 15 Coffee Farmers, 4 Baristas, 2 Coffee Sorters, 1.537 coffee enthusiasts, and business partnerships with 35 B2B and B2C partners. In general, the Community Satisfaction Index (CSI) for the overall program of PT. Pertamina Geothermal Energy Tbk. Area Kamojang including The Canaya Geothermal Coffee scored 82.7, which falls under the A category for service quality, which is classified as very satisfied.

4.6 Replicability Evaluations

4.6.1 Relevance, Impact, Efficiency

The implementation of coffee drying methods using geothermal dry house by PT Pertamina Geothermal Energy Tbk Area Kamojang (PGE Kamojang) holds significant relevance in terms of replicability. This is due to several factors:

1. Available Technology: Geothermal heating technology has proven to be effective and available in many regions with geothermal potential. Therefore, this method can be easily replicated in other areas with similar geothermal potential.
2. Scalability: The coffee drying method using geothermal heaters can be adapted to different production scales. It can range from small-scale for local coffee farmers to large-scale for larger coffee processing industries.
3. Potential Environmental Impact Reduction: By reducing reliance on fossil fuels or wood for coffee drying, the use of geothermal heaters can help reduce negative environmental impacts, such as greenhouse gas emissions and deforestation.

Furthermore, in term of impact and efficiency, the replication of this geothermal dry house provides significant impact and enhances efficiency in the production process.

1. Positive Environmental Impact: The use of geothermal heaters in the coffee drying process has a positive environmental impact. By reducing the use of fossil fuels or wood, this method helps reduce greenhouse gas emissions and alleviate pressure on forests as a source of fuelwood.
2. Operational Efficiency: Compared to conventional drying methods that rely on weather conditions, the use of geothermal heaters can enhance operational efficiency. The availability of stable and controllable heat energy accelerates the coffee drying process without significantly affecting its quality.
3. Social and Economic Impact: Increased efficiency in the coffee drying process can have positive social and economic impacts on coffee farmers and stakeholders in the coffee sector. Simplifying the drying process can enhance productivity and product quality, which in turn can increase income and competitiveness for local coffee farmers.

Thus, the implementation of coffee drying methods using geothermal dry house is not only relevant in terms of replicability but also has significant positive impacts on the environment, operational efficiency, and socio-economic well-being of local communities. This makes it a promising solution in efforts to enhance sustainability and efficiency in the coffee industry.

4.6.2 Cost Effectiveness (No, Low, High Cost)

The Canaya Geothermal Coffee's sustainability hinges on the harmonization of various elements, including equipment, steam provision, and community backing. While no specific equipment issues are highlighted, challenges persist concerning steam resources and social support, common hurdles in geothermal endeavors. Hence, establishing a green living ecosystem serves as a savvy strategy to mitigate the eco-social quandary that could undermine operational stability if neglected.

Securing a sustainable and dependable steam supply is paramount for The Canaya Geothermal Coffee's long-term prosperity. This entails efficient resource management, routine well upkeep, and continuous reservoir health monitoring. Furthermore, fostering social backing from the local community is vital for ensuring project

sustainability. Cultivating robust community bonds and addressing their concerns are crucial steps toward garnering support and fostering trust.

4.6.3 Sustainability of Project

The integration of the green living ecosystems concept into The Canaya Geothermal Coffee's business process marks a pivotal breakthrough in both project development and dry house operation. It is advisable to initiate this process during the inception phase. However, it's worth noting that introducing these sustainable practices during the operational phase of an existing geothermal dry house is never too late. Given the significant threat of declining well performance in geothermal operations, efforts to mitigate this risk by sustaining the ecosystem surrounding the geothermal reservoir are prudent measures.

4.6.4 Others

Geothermal dry house has the advantages of being weather-independent, available heat around the clock, and naturally controlled temperature and humidity. This method is similar to the conventional drying method but relies on geothermal as a constant heat supply instead of the fluctuating sun radiation. Moreover, the existing dry house has been improved to mitigate sulfur smell issues by using double door access and a distant steam exhaust. In this study, the existing geothermal dry house for coffee drying in Kamojang is evaluated from the technical and business aspects. The implementation of geothermal Dry house offers a sustainable, efficient, and cost-effective alternative to conventional heating and cooling systems, with the potential to reduce carbon emissions, enhance energy independence, and stimulate economic development. Additionally, this approach can serve as a strong defense for the company against social problems.

4.7 Amount of Fossil Energy Avoided

The Geothermal Dry House using geothermal steam as dry house or equivalent to 25,229 MW and reducing greenhouse gasses 21,949 tCO2/year.

5. CONCLUSION

Geothermal dryhouse has the advantages of being weather-independent, available heat around the clock, and naturally-controlled temperature and humidity. This method is similar to conventional drying method but relying on geothermal as a constant heat supply instead of the fluctuative sun radiation. Moreover, the existing dryhouse has been improved to mitigate sulfur smell issues by using double door access and a distant steam exhaust. In this study, the existing geothermal dryhouse for coffee drying in Kamojang is evaluated from the technical and business aspects. Based on technical evaluation, the required heating power is 10.94 kW with a heat transfer rate per unit length of heating pipe is 0.2618 kW/m. Thus, the required length of heating pipe is 41.79 m which has been fulfilled by the length of the existing heating pipe with a length of 43.5 m. The results indicated that the heating pipe was able to increase the dryhouse temperature. However, the condensate buildup inside the heating pipe reduces the dryhouse temperature minutes after the heating pipe operation. Therefore, it is responded by installing two stream traps, each installed at the inlet and outlet of the drying house to reduce condensate in the steam entering the drying house and remove the condensate formed while the steam is in the drying house. Subsequently, the heating pipe was tested operational twice on 16-17 January and 27-28 April 2023. On Trial 1, the heating pipe performance was not optimal due to condensate buildup inside the heating pipe. Therefore, steam traps were installed to reduce the condensate buildup. As a result, on Trial 2, the heating pipe performance was better, which was indicated by the higher and stable dryhouse temperature during the night. On Trial 3, the dryhouse temperature during the night was maintained higher than on Trial 2. This indicates that the technical improvements managed to improve the heating pipe’s performance on maintaining the dryhouse temperature. After all, the geothermal dryhouse can accelerate drying time significantly, up to 75% faster than conventional methods. This increased efficiency can lead to higher productivity and throughput in coffee drying processes.

Keywords: geothermal, tax incentives, tax allowance, tax holiday, tax credit, production tax credit, investment tax credit

ABSTRACT

Geothermal projects require substantial initial investments, largely due to costly exploration and infrastructure development. This capital-intensive nature not only extends the payback period but also increases financial risk, making external funding crucial. Tax incentives such as credits and deductions can significantly lower the investment threshold by reducing tax liabilities and enhancing the project's appeal to investors. Currently, Indonesia offers tax incentives for the geothermal industry through mechanisms such as tax holidays and tax allowances, primarily applying tax deduction methods. In contrast, the United States has implemented tax credit mechanisms, notably the Production Tax Credit (PTC) and Investment Tax Credit (ITC), which provide a more advantageous financial benefit. Tax credits are inherently more beneficial than deductions because they offer dollar-for-dollar tax savings, directly reducing tax liability. Furthermore, the United States also utilizes tax credit monetization, including tax credit transfers and tax equity financing. These mechanisms convert non-cash tax benefits into immediate capital, enhancing project cash flows—a critical advantage for geothermal projects with high capital costs.

Implementing a similar tax credit and monetization framework in Indonesia could provide substantial benefits over the current tax reduction incentives. This paper aims to explore the lessons learned from the US tax credit mechanism and assess its applicability in Indonesia to enhance the effectiveness of tax incentives for the geothermal sector.

1. INTRODUCTION

The development of geothermal projects can be divided into several phases: the preliminary survey, exploration and delineation drilling, development drilling and EPC (Engineering, Procurement, and Construction) for the power plant, followed by steam production and maintenance. Figure 1 illustrates the typical stages of a geothermal project along with its associated risk profile and investment cost. It highlights the high risk and substantial investment required to develop a geothermal project.

Despite the substantial capital needed for geothermal project development, investment in Indonesia's geothermal sector showed a decreasing trend from 2016 to 2021. This decline can be attributed to both internal and external factors related to project conditions. Internally, the significant capital requirement during the EPC phase is a major obstacle. Externally, aspects such as market trends, regulatory frameworks, economic stability, and fiscal incentives significantly influence the investment landscape for geothermal projects.

This paper aims to explore new fiscal incentives to boost geothermal investment in Indonesia by learning from the success of the US tax credit mechanism. Specifically, the study investigates the US Production Tax Credit (PTC) and Investment Tax Credit (ITC) models, seeking to identify key elements that could be adapted to enhance Indonesia's fiscal policies. The goal is to propose a tax incentives alternative that can effectively reduce the financial risks and barriers faced by geothermal developers in Indonesia.

2. TAX INCENTIVES BENCHMARK FROM US GEOTHERMAL INDUSTRY

As of 2023, the United States has reached an installed geothermal capacity of 3,771 MW, marking its initiation with the first geothermal power plant (GPP) operational at the Geysers in 1971. This positions the United States as a global leader in geothermal energy. The growth of the U.S. geothermal sector has been significantly influenced by two main factors: supportive federal and state-level policies and the economic dynamics shaped by natural gas prices and the development of the oil and gas industry.

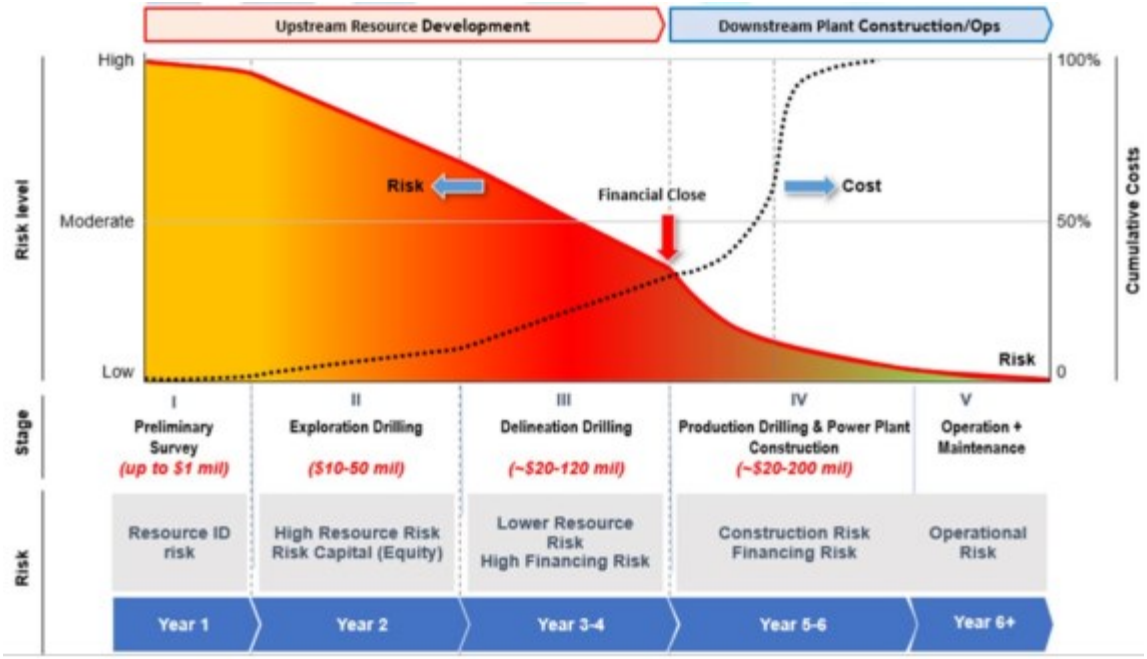

Figure 1: Geothermal development project phases and typical risk profile (modified from World Bank, 2019).

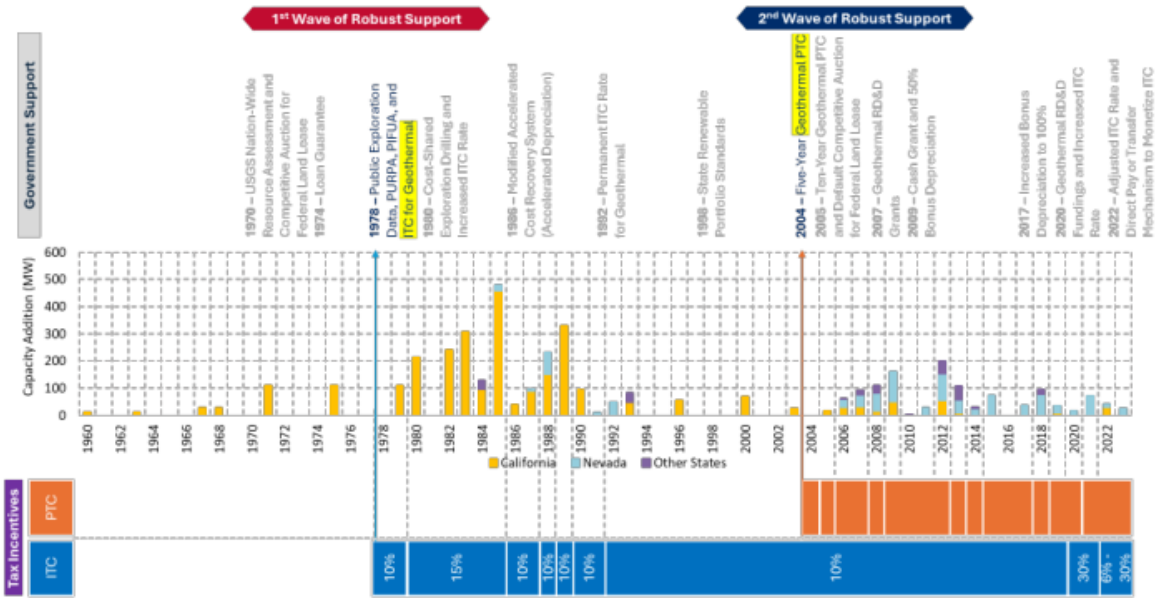

Figure 2: Annual Installed Geothermal Capacity and Key Federal Policy Milestones.

Federal and state policies have played a crucial role in fostering geothermal development through two major policy waves. The first wave, initiated in the 1970s, featured the introduction of federal land leasing regulations tailored for geothermal developments, exploration de-risking programs, and open access to exploration data. This period also saw the introduction of an investment tax credit (ITC) and the establishment of markets for investor-operated GPPs. The second wave, starting in the 2000s, implemented royalties, cash grants, a production tax credit (PTC), and other state-level incentives aimed at supporting geothermal power producers. These policies further mandated that utility companies procure a specified portion of their electricity from renewable sources.

One of the federal policies applied to geothermal energy in the U.S. is the use of tax incentives, particularly the ITC and PTC. The ITC, which offers a 10% credit for geothermal projects, was first enacted in 1978, while the PTC was introduced in 2005 specifically for geothermal energy. These federal renewable tax credits have undergone numerous extensions, modifications, and renewals, with significant changes introduced by the Inflation Reduction Act of 2022 (IRA 2022). This act expanded eligible technologies, extended the expiration date, modified the scheduled step-down in value, provided new bonus credits, and established new criteria to qualify for the full credit (DSIRE, 2023; U.S. Department of Energy, 2024).

Figure 1 illustrates the annual installed geothermal capacity alongside key federal policy milestones, including cash grants, loan guarantees, and tax incentives. The observed growth in the U.S. geothermal installed capacity, which aligns with the implementation of the Investment Tax Credit (ITC) and Production Tax Credit (PTC), highlights the potential effectiveness of these tax credit mechanisms. This connection prompts a compelling opportunity to study these frameworks in detail to assess their applicability in Indonesia. By examining the mechanisms and benefits of the ITC and PTC, Indonesia can consider adopting similar strategies to attract investment and accelerate the development of its geothermal sector.

2.1 Investment Tax Credit (ITC)

The Investment Tax Credit (ITC) reduces the tax liability by a percentage of the eligible investment cost during the tax year. It is an upfront tax credit that does not vary by system performance. For geothermal electricity, the ITC is given in the year of the Commercial Operation Date (COD) of the geothermal power plant.

Under the IRA 2022, the base ITC rate for geothermal is 6% of the eligible investment cost. The ITC rate can increase to 30% if the geothermal developer meets the "Labor Requirements1". Additionally, there are bonus credits that can be accessed to maximize the ITC rates, such as:

1. **Domestic content bonus**: an additional 10% of ITC rates.
2. **Energy community bonus**: an additional 10% of ITC rates.

Labor requirements including: 1) Prevailing wages requirements: for the first five years of the project for the ITC must be paid at the prevailing rates of that location; 2) Apprenticeship requirements: projects must ensure that 10-15% of total labor hours are performed by qualified apprentices (DSIRE, 2023).

The ITC is determined based on the plant's investment cost, making it crucial to understand which expenses qualify for inclusion to accurately calculate the project's eligible tax credit. The eligible investment cost for ITC includes equipment used to produce, distribute, or utilize energy derived from a geothermal source. This includes all equipment involved in the generation and distribution of geothermal energy within the plant. However, it excludes equipment used for the transmission of electricity from the plant to the grid, such as transmission lines.

2.2 Production Tax Credit (PTC)

The Production Tax Credit (PTC) is a per kilowatt-hour (kWh) tax credit for electricity generated by geothermal power plant for the first 10 years of a system's operation. It reduces federal income tax liability and is adjusted annually for inflation based on the GDP implicit price deflator from 1992.

Under the IRA 2022, the base PTC rate for geothermal is 0.55 cents USD per kWh, which can increase to 2.75 cents USD per kWh if the "Labor Requirements" are met. Additionally, bonus credits can further enhance the PTC rates:

1. **Domestic content bonus**: an additional 0.1 cents USD per kWh.
2. **Energy community bonus**: an additional 0.1 cents USD per kWh.

2.3 Enhancement Features for ITC and PTC

In addition to maximizing ITC or PTC rates by meeting labor requirements and obtaining bonus credits, geothermal developers can also enhance their tax credit benefits through the use of carryforward or tax credit transfer mechanisms. These mechanisms are designed to ensure that any unused tax credits from the current tax year can be fully utilized.

2.3.1 Tax Credit Carry-forward

The ITC and PTC can be carried forward if the tax liability is lower than the credit earned within the tax year. This mechanism allows taxpayers to apply unused tax credits from the current tax year to offset tax liabilities in future years, ensuring they can fully benefit from the credits even when their current-year tax liability is insufficient to utilize the entire amount.

The carryforward period for these credits typically ranges from 20 to 22 years after the tax credit is earned. The specific duration and rules governing the application of these credits may vary based on the particular tax credit and jurisdiction. At the end of the carryforward period, one-half of any unused credit can be deducted, with the remaining amount expiring. However, carryforward credits are not eligible for transferability, meaning it cannot be sold or transferred to another taxpayer.

2.3.2 Tax Credit Transfer

In the United States, geothermal developers with ITC or PTC are eligible to monetize their unused tax credits through a tax credit transfer mechanism. This mechanism allows developers with unused tax credits to sell or transfer all or a portion of these credits to an unrelated eligible taxpayer. This process enables the developer to

monetize their unused tax credits, while the purchasing taxpayer can utilize the acquired credits to offset their own tax liabilities.

Figure 3: Illustration of Tax Credit Carryforward Mechanism.

Terms and conditions for geothermal developers with ITC/PTC looking to monetize their tax credits are as follows:

1. The seller may sell the tax credit at a discounted price.
2. The benefit of the depreciation bonus from the tax credit cannot be transferred.
3. These payments are not considered gross income for federal tax purposes.
4. The carried forward credits are not eligible for credit transfer.
5. The portions of credits can be sold to multiple buyers within the same years.
6. The transfer of only the bonus credit amount of a tax credit is not permitted.

Payments for the credit transfer must be made in cash and are not considered gross income for federal purposes, meaning no federal taxes are owed on receiving the payment, and no deduction is available to the tax credit buyer for making the payment.

3. EXISTING GEOTHERMAL TAX INCENTIVES IN INDONESIA

The Government of Indonesia has introduced corporate income tax incentives specifically targeted at the geothermal industry, including tax holidays and tax allowances. These incentives are designed to enhance the attractiveness of geothermal projects by reducing the financial burden on companies, thereby promoting increased investment and improving profitability within the sector.

This section aims to examine the current geothermal corporate income tax incentives, focusing on the effectiveness of these incentives for geothermal project in Indonesia.

3.1 Tax Holiday

A tax holiday is one of the investment incentives provided by the Government of Indonesia, regulated by PMK No. 35 of 2018. This incentive offers a corporate income tax exemption for a period ranging from 5 to 20 years. The duration of the tax holiday is determined based on the amount of investment costs, as shown in Table 1.

Table 1: Tax Holiday Period based on the Total Investment Cost.

No	Total Investment Cost	Tax Holiday Period
1	IDR 0.5 to 1 trillion	5 years
2	IDR 1 to 5 trillion	7 years
3	IDR 5 to 15 trillion	10 years
4	IDR 15 to 30 trillion	15 years
5	More than IDR 30 trillion	20 years

For geothermal project with an investment exceeding IDR 0.5 trillion, developers are eligible for a 50% tax reduction for two years during the transition period following the initial tax holiday. Additionally, geothermal developers with an investment of more than IDR 0.1 trillion can receive a 50% tax reduction for the first five years of operation, followed by a 25% tax reduction for the subsequent two-year transition period.

3.2 Tax Allowance

Government Regulation No. 78 of 2019 (GR 78/2019) in Indonesia includes a tax allowance as one of its incentives to promote investment in various sectors, including geothermal energy. This tax allowance provides an investment tax deduction equivalent to 30% of the fixed capital investment, which is applied at a rate of 5% per

year over six years. Additionally, geothermal projects benefit from an eight-year depreciation period for both tangible and intangible assets. The geothermal industry is also eligible for a loss carryforward for up to five years, which can be extended to a maximum of ten years under certain conditions.

3.3 Study Literature on Effectiveness of Tax Holiday and Tax Allowance for Geothermal Project

While the government of Indonesia has attempted to attract investment in geothermal energy through tax holidays and tax allowances, numerous studies have highlighted the drawbacks of these incentives in attracting long-term investments, particularly for capital-intensive projects like geothermal energy development.

3.3.1 Limitations of Tax Holidays for Geothermal Project

The idea of a tax holiday is quite appealing as it provides a 100% reduction in corporate income tax for several periods, effectively serving as a tax exemption for those periods. However, tax holidays have several shortcomings as incentives to promote investments. According to several studies, the limitations of tax holidays are as follows:

1. Stotsky (2024) argues that tax holidays tend to attract short-term projects that yield quick returns rather than long-term investments. These long-term projects, which may offer greater value over time but do not generate profits in the early years, often find tax holidays less appealing as they do not benefit immediately from the tax exemption period.
2. Holland and Vann (1998) noted that tax holidays are less beneficial for significant capital-intensive projects, such as geothermal developments, which typically do not achieve profitability in the initial years. This misalignment between the tax holiday period and the financial realities of geothermal projects limits the effectiveness of such incentives.
3. Fadhillah et al. (2023) provide a case study that underscores the ineffectiveness of the current tax holiday structure for geothermal projects in Indonesia. The study demonstrates that the timing and design of these tax incentives do not align with the financial realities faced by geothermal developers. Without sufficient tax liabilities in the initial years, the tax holiday fails to provide the intended financial relief, thereby not enhancing project attractiveness or significantly reducing electricity generation costs.

These findings suggest that while tax holidays may be effective for certain types of investments, they are not well-suited for long-term, capital-intensive projects like geothermal energy development. To improve their efficacy, it is crucial to adjust the structure of tax incentives to better match the financial timelines and needs of these projects. This could potentially attract more sustainable investments and enhance the development of the geothermal sector in Indonesia.

3.3.2 Limitations of Tax Allowance for Geothermal Project

In the context of geothermal projects that do not have sufficient tax liabilities during the initial years of operation, tax allowance facilities become ineffective. Although tax allowances can be carried over, the carryover period of only five years is insufficient to accommodate the cash flow conditions of geothermal projects.

For example, Company A has a geothermal power plant with a capacity of 30 MW and a capital expenditure (capex) of 204 million USD. Company A plans to use a tax allowance at a rate of 6% for five years. Table 2 shows a simple simulation of the tax calculation for this project.

Table 2: Simplified Example of Tax Allowance in a Geothermal Project.

	Years of operation					
	1	**2**	**3**	**4**	**5**	**6**
Profit before tax	$-814	$-6,289	$-5,814	$-5,246	$-5,678	$-5,726
Tax allowance	$12,244	$12,244	$12,244	$12,244	$12,244	-
Tax amount	-	-	-	-	-	-

	Years of operation					
	7	**8**	**9**	**10**	**11**	**12**
Profit before tax	$-4,748	$-3,995	$-3,299	$-1,834	$-1,184	$1,088
Tax allowance	-	-	-	-	-	-
Tax amount	-	-	-	-	-	$266.21

The example above indicates that Company A does not have sufficient taxable income until the 12th year of operation, while the tax allowance period ends in the fifth year after COD. This underscores that the tax allowance cannot be utilized at all for the geothermal project developed by Company A. This observation aligns with Stotsky (2024), who noted that tax allowances are most beneficial to firms with existing income. Such firms can use the

incentives from new investments to shelter a portion of their income from tax. In contrast, firms with low income cannot benefit from the incentive until the investment starts generating income.

This finding suggests that the implementation of tax allowances for geothermal projects in Indonesia requires adjustments, such as extending the tax allowance period and/or extending the loss carryover period of the tax allowance itself.

4. DISCUSSION

4.1 Comparison of tax incentive mechanisms in Indonesia and the United States

There are notable contrasts in the tax incentives applied in the United States and Indonesia, particularly in the methods of taxation employed. Indonesia utilizes the tax exemption method for tax holidays and the tax deduction method for tax allowances, whereas the United States employs the tax credit mechanism. Essentially, a tax deduction is an amount that can be subtracted from a taxpayer's gross income, thereby reducing the amount of income subject to tax. Deductions lower taxable income, and their value depends on the taxpayer's marginal tax rate. A tax exemption, on the other hand, excludes certain income from being taxed altogether. This means that the exempted income is not considered part of the taxable income. For instance, in Indonesia, geothermal projects which applied for tax holiday might be granted tax-exempt status for a specified period, thus encouraging investment in those areas by completely removing the tax burden on that income. In contrast, a tax credit is a direct reduction of the tax owed, rather than a reduction of taxable income. It reduces the tax liability dollar-for-dollar, making it potentially more beneficial than a deduction or exemption, as it directly lowers the amount of tax that needs to be paid. The summary of differences between tax deductions, tax exemptions, and tax credits is shown in Table 3.

Table 3: Summary of The Difference between Tax Deduction, Tax Exemption, and Tax Credit.

Aspects	Tax Exemption	Tax Deduction	Tax Credit
Definition	Specific income excluded from being taxed	An amount subtracted from gross income to reduce taxable income	A direct reduction in the amount of tax owed
Function	Reduces gross income, hence lowering taxable income	Lowers taxable income; value depends on taxpayer's marginal tax rate	Reduces tax liability dollar-for-dollar
Impact	Excludes certain types of income from taxation entirely	Reduces the amount of income subject to tax, thereby lowering tax liability	Directly decreases the total tax owed, potentially resulting in a refund
Examples	Tax Holiday	Tax Allowance	1. Investment Tax Credit 2. Production Tax Credit

To better understand the difference between a tax deduction and a tax credit, consider two companies, Company A and Company B, each with a taxable income of $1,000,000. Both are eligible for a $100,000 benefit, but Company A receives a tax deduction, while Company B receives a tax credit. Table 4 shows the simplified calculation for each case.

Table 4: Simplified Example of Tax Deduction and Tax Credit Mechanism.

Company	Tax Incentive	Original taxable income	Tax deduction	Taxable income after tax deduction	Income tax rate	Tax liability	Tax credit	Tax owed
Company A	Tax deduction	$ 1,000,000	$ 100,000	$ 900,000	25%	$ 225,000	-	$ 225,000
Company B	Tax credit	$ 1,000,000	-	$ 1,000,000	25%	$ 250,000	$ 100,000	$ 150,000

The example above demonstrates that tax credits are generally more advantageous than deductions because they provide a dollar-for-dollar reduction in tax liability, directly decreasing the amount of tax owed. This is in contrast to tax deductions, which merely reduce the taxable income upon which the tax liability is calculated. As shown, while both deductions and credits offer tax benefits, tax credits typically have a more substantial and straightforward impact on lowering the overall tax burden.

4.2 Potential Benefits in Adopting Tax Credit Transfer Mechanism

In addition to tax credit mechanisms such as ITC and PTC, another beneficial approach that can be adopted from U.S. tax incentives is the tax credit transfer mechanism. This mechanism allows developers to fully utilize the tax

facilities. Furthermore, several potential benefits can be achieved through the implementation of tax credit transfers:

1. **Increased Liquidity for Developers**: Tax credit transfers allow developers to sell unused tax credits to other entities,providing immediate capital that can be reinvested in their projects. This is particularly beneficial for geothermal projects,which require substantial upfront investment.
2. **Attracting New Investors**: Tax credit transfers can attract a wider range of investors, including those who may not bedirectly involved in geothermal energy but are interested in purchasing tax credits to offset their own tax liabilities.
3. **Boosting Project Viability**: The ability to transfer tax credits can make geothermal projects more financially viable byreducing the effective cost of capital and improving project economics.
4. **Enhanced Return on Investment**: Developers can achieve a better return on investment by converting non-cash taxbenefits into actual cash flow, thus making projects more attractive to stakeholders.

4.3 Challenges and Opportunities in Adopting US Tax Credit Mechanisms in Indonesia

Adopting tax credits for geothermal energy projects in Indonesia offers significant opportunities but also presents several challenges that need to be addressed for successful implementation.

The potential opportunities of adopting US tax credit mechanisms are as follows:

1. Direct Reduction in Tax Liability: Tax credits are more advantageous than deductions because they provide a dollar-for-dollar reduction in tax liability, directly decreasing the amount of tax owed. This makes tax credits a powerful tool for improving the financial attractiveness of geothermal projects.
2. Enhanced Utilization of Tax Facilities: Developers can fully utilize tax facilities through several enhancement features as follows:
    a. Tax Credit Transfer: Allows developers to sell unused tax credits to other entities, providing immediate capital that can be reinvested in their projects. This improves liquidity and project cash flow, crucial for the capital-intensive nature of geothermal projects.
    b. Carryforward Provisions: Enable developers to use tax credits that exceed their current tax liability in future years, ensuring that the benefits of the credits are not lost due to initial non-profitability.
    c. Credit Bonus: Additional incentives can be provided for meeting specific criteria, such as using local resources or achieving certain production milestones, further enhancing the attractiveness of investments.
3. Boosting Investment and Economic Growth: The introduction of tax credits can attract a broader range of investors, including those not directly involved in geothermal energy but interested in purchasing tax credits to offset their tax liabilities.

Despite the significant opportunities presented by adopting U.S. tax credit mechanisms for geothermal projects in Indonesia, several challenges must be addressed to implement such a new tax incentive effectively. These challenges include:

1. Defining Eligible Expenditures: One of the major technical issues in adopting the Investment Tax Credit (ITC) is defining eligible expenditures. Achieving a precise definition is crucial to direct the incentive to the desired activities and minimize revenue "leakage." At the same time, it is essential to provide taxpayers with certainty regarding the applicability of the incentive (Holland & Vann, 1998).
2. Setting the Appropriate Rate: Determining the appropriate rate for the tax credit is complex. The rate must be attractive enough to incentivize investment without causing significant revenue loss for the government. Striking this balance is crucial to ensure the effectiveness of the tax credit.
3. Policy and Regulatory Changes: Implementing a new tax credit system requires changes to existing policies and regulations. Ensuring policy stability and consistency is vital to maintaining investor confidence. Frequent changes or uncertainties in tax policy can deter long-term investments.
4. Administrative Implementation: Introducing tax credits involves setting up robust administrative systems to manage, monitor, and enforce the new policies effectively. This includes handling applications, ensuring compliance, and processing claims, all of which can be resource-intensive.

While the adoption of tax credits for geothermal energy in Indonesia presents notable opportunities to stimulate investment and advance renewable energy goals, it also involves significant challenges that need to be carefully managed. Addressing these challenges through clear definitions, appropriate rates, robust administration, and policy stability can help maximize the benefits of tax credits and support the sustainable development of Indonesia’s geothermal sector.

5. CONCLUSION AND PATH FORWARD

Currently, the implementation of tax holidays and tax allowances as incentives in Indonesian geothermal projects exhibits several shortcomings that hinder developers from fully utilizing these benefits. Numerous studies have highlighted the need for adjustments, such as extending both the tax holiday and the loss carryover periods for tax allowance facilities.

Additionally, this study proposes adopting the U.S. tax credit mechanism, which includes ITC and PTC, along with enhancement features such as bonus credits and credit transferability. Tax credits offer a dollar-for-dollar reduction in tax liability, directly reducing the amount of tax owed. According to the authors, this makes the tax credit scheme a more advantageous option compared to the tax deduction scheme used in tax allowances. Furthermore, implementing the enhancement feature of credit transfer could allow developers to maximize the use of the tax facility during the early operational phase of geothermal power plants, which typically do not yet have sufficient tax liabilities. This tax credit transfer mechanism could also provide an alternative for developers to generate revenue during the initial operational phase.

Moreover, it is essential to conduct further assessments to evaluate the impact of utilizing tax credits on the financial feasibility of projects. Such analysis will provide a clearer understanding of both the benefits and the drawbacks associated with this form of tax incentive. There is also a need for more comprehensive studies aimed at developing a policy brief and a framework to facilitate the implementation of tax credits in Indonesia, ensuring that these incentives effectively support the development of the sector.

Keywords: Geothermal drilling cost in Indonesia, geothermal drilling unit cost (GDUC), geothermal drilling cost component

ABSTRACT

The development of geothermal energy as a clean and sustainable energy source in Indonesia faces significant challenges due to the high costs associated with drilling. This paper provides a detailed analysis of geothermal drilling costs in Indonesia by examining actual and historical data from various projects. The study addresses the difficulties in accessing comprehensive cost data due to the absence of an integrated database, the confidential nature of drilling costs, and the lack of standardized reporting and costing structures. Despite these challenges, the study compiles data from 254 drilling records between 2011 and 2023, normalizing costs to 2023 values using the Producer Price Index (PPI). This study indicates a wide cost range from 1,300 to 22,000 USD per meter, with most costs clustering between 2,733 and 4,549 USD per meter and a median of 3,432 USD per meter.

The study also highlights the impact of drilling difficulties and failures on cost outliers, providing insights into the highest and lowest drilling costs recorded. The findings underscore the need for improved data management and standardization in geothermal drilling in Indonesia to enhance cost efficiency and support the sustainable development of geothermal energy.

1. INTRODUCTION

The development of geothermal energy, a clean and sustainable energy source, is often impeded by the substantial costs involved in drilling. This paper presents a detailed analysis of geothermal drilling costs in Indonesia, aiming to provide a comprehensive understanding of these expenses by examining the actual and historical drilling costs of various projects.

1.1 Challenges in Accessing Geothermal Drilling Cost Data in Indonesia

One method to identify these costs in Indonesia is through a database that includes data from all developers. However, no such geothermal drilling database currently exists in Indonesia, presenting a significant challenge in gathering accurate data. Consequently, the quality of our analysis depends on the data we can access. Accessing geothermal drilling cost data in Indonesia is notably challenging. Several factors contribute to this difficulty:

1. **Absence of a Geothermal Drilling Database**: No integrated database currently exists for geothermal drilling, complicating the collection of comprehensive data.
2. **Confidential Nature of Drilling Costs**: Developers rarely disclose geothermal drilling costs due to their confidential nature, hindering the free flow of information necessary for effective data gathering, benchmarking, and analysis. Interviews suggest there is no clear rationale for this secrecy, given that drilling data are specific to each field and operator.
3. **Scarcity of Publications**: There is a noticeable lack of comprehensive publications on geothermal drilling costs, which may be linked to the confidential nature of such data. This scarcity limits the availability of publishable drilling cost data. Additionally, some existing publications offer cost estimates for hypothetical wells, which are unsuitable for this analysis.
4. **Incomplete Data in Reports**: Many reports do not provide a complete breakdown of total drilling costs, resulting in an inadequate dataset for detailed cost analysis. This issue stems from the absence of a standard reporting requirement enforced by the Indonesian government for documenting geothermal drilling activities.
5. **Lack of Standardized Costing Structure**: The Indonesian government has not mandated developers to collect and submit drilling data in a standardized format, complicating the task of conducting accurate cost component analysis.

1.2 Available Geothermal Drilling Data

Despite the challenges in obtaining comprehensive geothermal drilling cost data, this study has made a concerted effort to compile information from various sources. A total of 254 drilling records from Indonesia, spanning the years 2011 to 2023, were acquired. To ensure consistency and relevance, all data was normalized to 2023 values using the Producer Price Index (PPI) from the US Department of Labor's Bureau of Labor Statistics.

Of the 254 Indonesian drilling data records collected, only 51 wells have a detailed cost breakdown. The cost breakdown presented in this study includes only rig costs, tangibles, and drilling services. It does not cover mobilization and demobilization costs, nor site preparation expenses. Given that approximately 825 geothermal wells have been drilled in Indonesia from 1970 to 2023 (Purwanto et al., 2021; Geoenergis, 2023), the dataset used in this study is relatively limited. This limitation highlights the urgent need for improvements in the storage and management of geothermal drilling data in Indonesia.

2. GEOTHERMAL DRILLING WELL DEPTH TREND IN INDONESIA

To accurately assess the baseline costs of geothermal drilling in Indonesia, this study begins with understanding the typical well depths within the country is essential. This knowledge is key, as the depth of the well is a critical factor that significantly impacts the overall drilling costs.

Figure 1 shows the well depth distribution of 254 geothermal wells in Indonesia. The distribution shows a wide variation in well depths, stretching from below 500 meters to over 3,000 meters. However, the frequency of wells noticeably diminishes as the depth surpasses 2,500 meters, suggesting that wells within this range are less common. Additionally, wells that are deeper than 3,000 meters are relatively rare. Overall, 70% of geothermal well depth in Indonesia ranging from 1,600 – 2,800 meters with average depth of 2,254 meters.

Figure 1 also reveals that there are several wells with depths less than 1,200 meters measured depth (mMD), which are considered shallow and shallower than the typical depth of the top of the geothermal reservoir in Indonesia, approximately 1,200-2,000 meters. Further analysis of drilling and chronological data indicates that all these wells failed to reach their target depth due to various reasons, such as stuck pipes, or running out of budget that prevented them from reaching the target depth. These unsuccessful wells can impact the statistical analysis of drilling costs, for instance, in USD/m analysis, as they may inflate the USD/m value due to their shallow depth.

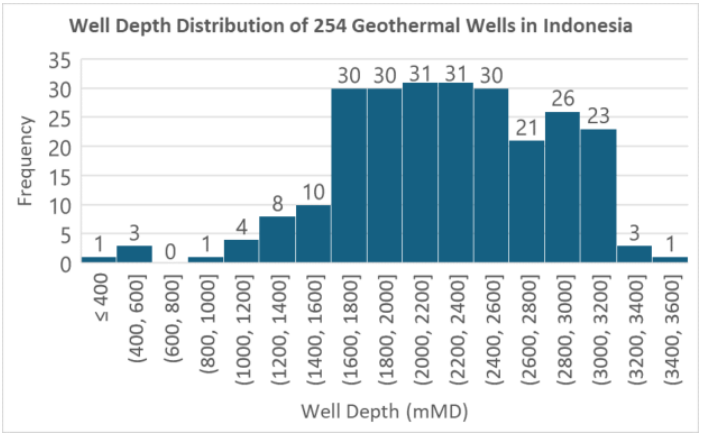

Figure 1: Histogram of Well Depth from 254 Geothermal Wells in Indonesia.

According to (Sanyal, et al., 2011a), depth is considered the primary determinant of the drilling cost of a geothermal well, with the cost typically increasing exponentially as depth increases in any country. Therefore, to understand the baseline trend of total geothermal drilling costs in Indonesia, a statistical analysis was conducted on the distribution of these costs in relation to well depth. Additionally, Lukawski (2016) found that, with increasing depth, drilling problems escalate, not in a linear fashion, but significantly at specific depths within the reservoir zone. Therefore, the addition of drilling depth must be carefully considered in terms of risk, cost, and benefit.

3. GEOTHERMAL DRILLING COST TREND IN INDONESIA

Figure 2 illustrates the distribution of total drilling costs of 254 geothermal wells in Indonesia. The drilling cost data distribution presented reveals a scattered trend with a wide range of total drilling costs for geothermal wells in Indonesia, varying significantly from 1 million to 25 million USD per well. This extensive variability poses challenges for drilling engineers in establishing a definitive baseline for drilling costs for planning purposes.

Concurrently, this significant fluctuation suggests that there are opportunities for Indonesia to enhance the efficiency of its geothermal drilling expenses.

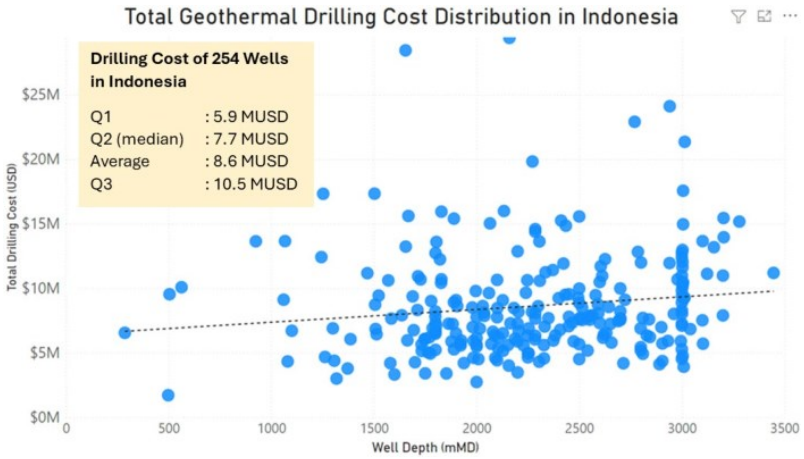

Figure 2: Scatter Chart of Total Geothermal Drilling Cost of 254 Wells in Indonesia.

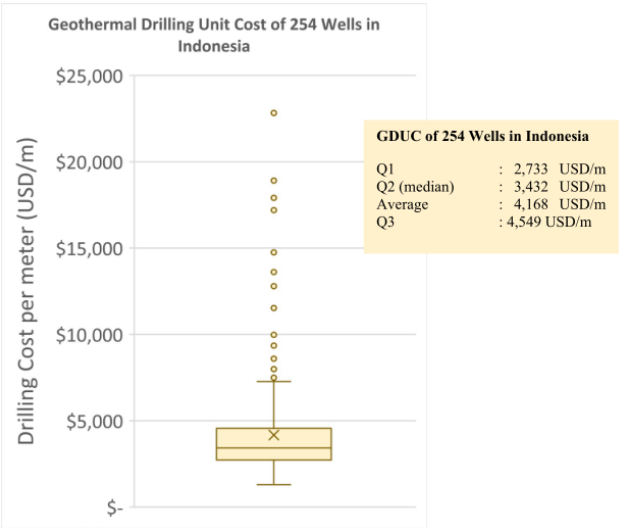

Figure 3: Box Plot of Geothermal Drilling Unit Cost in Indonesia.

One way to measure geothermal drilling performance is by using Geothermal Drilling Unit Cost (GDUC) as suggested by Zuhro and Arif (2015). The GDUC measures geothermal drilling performance in USD/m, with the intention to be able to compare the drilling cost between wells with different depth. Figure 3 shows the distribution of Geothermal Drilling Unit Cost (GDUC) in Indonesia. The box plot reveals a wide variation in the distribution of GDUC, with figures ranging from 1,300 to 22,000 USD per meter per well. It is also noted that wells costing more than 7,000 USD per meter are rare, representing outliers in this dataset. Given the dataset's susceptibility to outliers, the median is utilized as a more suitable measure to represent the drilling cost data, as it is less affected by these extreme values. Overall, the typical drilling cost range in Indonesia is fall within the interquartile range of 2,733 to 4,549 USD per meter with median of 3,432 USD per meter.

4. GEOTHERMAL DRILLING COST COMPONENT

In addition to understanding the trends in drilling costs per well, it is important to understand the specific components of these costs. Analyzing these cost components is crucial for identifying which components have the largest share and the most significant impact on geothermal drilling projects.

This section examines the recent trends in geothermal drilling costs, focusing on key contributors and their influence on overall project budgets. By analyzing these trends, geothermal companies can better manage costs and improve operational efficiency, leading to more successful drilling projects.

In this study, an analysis of the cost component distribution was conducted using data from 51 drilling projects. It was found that each company has different systems for classifying cost components. Therefore, this study attempts to classify drilling cost components based on major drilling elements, as follows:

1. Rig.
2. Bit.
3. Wellhead.
4. Casing.
5. Drilling fluid.
6. Cementing.
7. Directional drilling.
8. Aerated drilling.
9. Fuel.
10. Other costs, which include expenses other than the eight cost components mentioned above. These expenses consist of various smaller cost items, each of which contributes a relatively low percentage (ranging from less than 1% to no more than 3%) to the total drilling cost. Together, these "other costs" make up around 20% of the total drilling cost.

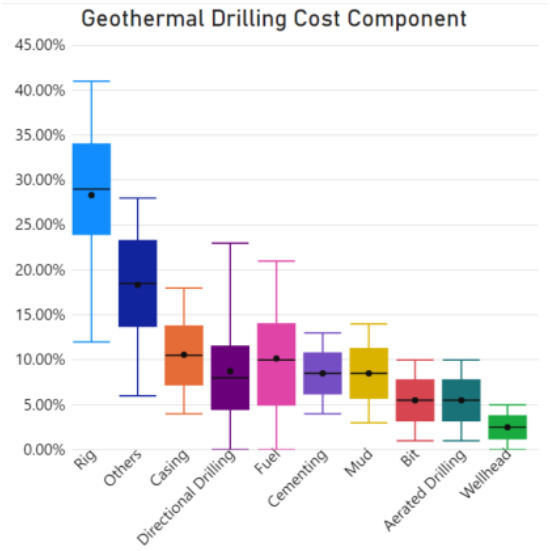

Figure 4: Percentage Distribution in Geothermal Drilling Cost Component.

Figure 4 presents a box plot showing the percentage distribution of drilling cost components based on data from 51 wells. The analysis indicates that the most substantial contributors to drilling costs are the drilling rig, casing, directional drilling, cementing, and drilling fluid. "Other costs" are not considered as substantial contributors to the drilling cost component, as they consist of a group of different services and/or materials.

Table 1: Summary of Percentage Distribution in Geothermal Drilling Cost Component.

No	Cost Component	Percentage of Cost Contribution (%)			
		Q1	Q2	Average	Q3
1	Rig	24	29	28	34
2	Casing	7	10	10	14
3	Directional drilling	4	8	9	11
4	Fuel	5	10	10	14
5	Cementing	6	8	8	10
6	Drilling fluid (mud)	5	8	8	11
7	Aerated drilling	3	5	5	7
8	Bit	3	5	5	7
9	Wellhead	1	2	2	3
10	Other costs	13	18	18	23

Table 3 summarizes the distribution of drilling cost components in Indonesian projects. The data reveals that the largest cost components are rig costs (24 – 34%), casing (7 – 14%), directional drilling (4 – 11%), fuel (5 – 10%), and cementing (6 – 10%). Collectively, these top five components account for approximately 80% of the total drilling cost. This observation is consistent with Pareto's Principle, often summarized as "80% of the effects arise from 20% of the causes." Should this pattern of cost distribution persist across various geothermal drilling operations in Indonesia, it would imply that drilling teams ought to prioritize the management of principal service

contracts that account for over 80% of the drilling costs. This approach suggests a strategic focus on key areas of expenditure rather than an equal distribution of resources and efforts across all contracts.

5. DRILLING COST OUTLIER

Figure 5 shows the distribution of geothermal drilling costs in Indonesia and highlights the presence of outlier data. The outlier data were identified using the 1.5 * IQR rule, a common statistical method that considers a data point an outlier if it is more than 1.5 times the interquartile range (IQR) above the third quartile or below the first quartile. Applying this rule to our dataset helps pinpoint unusually high costs in drilling operations. The analysis identified 13 wells with excessively high drilling costs, with a total expenditure of 176.5 million USD for these wells alone.

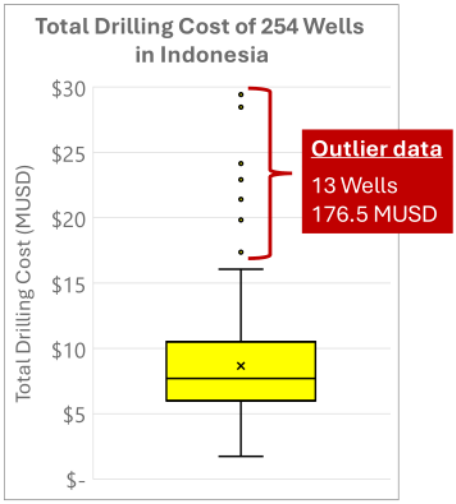

Figure 5: Outlier Data in the Box Plot of Geothermal Drilling Cost in Indonesia.

A further examination of the outliers reveals that the exceptionally high GDUC values are caused by several factors, such as:

1. **Recorded failed wells**. In the data presented, there are several wells that do not reach the total depth (TD) or reservoir depth, resulting in wells with very shallow depths. These wells are usually failed and non-productive ones, which are then decided to be abandoned before reaching the TD. This shallow well depth then influences the GDUC value or drilling cost per meter, where the smaller the well depth, the smaller the divisor of the total drilling cost, resulting in a high GDUC value.
2. **Drilling difficulties or drilling problems**. Some wells with high GDUC values are also influenced by drilling difficulties encountered during drilling, such as stuck pipes and blow-outs. These drilling difficulties then lead to Non-Productive Time (NPT) and additional drilling days. The longer the duration of drilling due to various drilling issues, the higher the well cost becomes, primarily due to the increasing rental costs of drilling rigs.

This subsection aims to analyze the causes of outlier data in the distribution of geothermal drilling costs in Indonesia, focusing on both the lowest and highest costs. The objective of this analysis is to gain a deeper understanding of the nature of geothermal drilling costs in Indonesia and to identify potential areas for improvement in cost efficiency.

5.1 Analysis on Excessively High Drilling Cost

In this study, the outlier data for excessively high drilling costs were identified using the 1.5 * IQR rule. This commonly used statistical rule states that a data point is considered an outlier if it is more than 1.5 times the interquartile range (IQR) above the third quartile or below the first quartile. Applying this rule to our dataset helps pinpoint unusually high costs in drilling operations.

Table 1 shows the outlier data for the highest total drilling cost in Indonesia. The data reveal that the most expensive drilling instance was recorded at 29.4 million USD for a well reaching a depth of ~2100 meters MD. Despite this significantly high cost, the well turned out to be not productive.

According to interviews, this highest drilling cost in Indonesia was attributed to multiple incidents of stuck pipes. The well accounted for 311.5 NPT (Non-Productive Time) hours or equal to 27% of the total drilling duration due to stuck pipe alone. This high NPT subsequently affected the addition of drilling days and caused a cost overrun.

Similarly, the second and third highest costs, at 28.4 million USD and 24.1 million USD respectively, were also due to multiple stuck pipe incidents in each well.

Table 2: Outlier Data of the Highest Drilling Cost in Indonesia.

No	Well Name	Well Depth (mMD)	Total Drilling Cost (USD)	Drilling Cost per meter (USD/m)	Well Status
1	Well A	~2100	$29,408,487	~$13,600	Non-productive
2	Well B	~1600	$28,441,465	~$17,100	Non-productive
3	Well C	~2900	$24,110,166	~$8,100	Productive
4	Well D	~2700	$22,904,286	~$8,200	Productive
5	Well E	~3000	$21,352,215	~$7,000	Productive
6	Well F	~2200	$19,824,782	~$8,000	Non-productive
7	Well G	~3000	$17,559,075	~$5,000	Productive
8	Well H	~1500	$17,335,170	~$11,500	Non-productive
9	Well I	~1200	$17,323,032	~$13,800	Non-productive
10	Well J	~2100	$15,988,860	~$7,400	Non-productive
11	Well K	~1800	$15,938,855	~$8,700	Non-productive
12	Well M	~1600	$15,605,100	~$9,300	Productive
13	Well N	~2500	$15,563,587	~$6,200	Non-productive

The data above further explains that geothermal drilling represents a high-risk venture, often encountering substantial cost overruns and even the possibility of no steam production. The analysis indicates that a significant contributor to these overruns is incidents of stuck pipes. Thus, the prevention of stuck pipes becomes important in drilling operations in geothermal projects to avoid these cost overruns.

5.2 Analysis on the Lowest Drilling Cost

In addition to observing outlier data with the highest drilling costs in Indonesia, observations were also made on the lowest drilling costs. The lowest value in this study was determined using a sorting method, where the collected dataset was sorted to identify the three lowest drilling costs. The objective of analyzing the three lowest drilling costs in Indonesia is to investigate the underlying factors contributing to these reduced expenses. This analysis seeks to identify any effective cost-saving strategies employed by the operators, with the intention of applying similar practices in future operations to achieve cost efficiency.

Table 3 shows a summary of the three lowest drilling costs in Indonesia. From this data, it is known that the cheapest drilling cost in Indonesia is 1.7 million USD for a depth of ~500 mMD. Given this very shallow depth, it can be ascertained that this well is a failed well that did not reach Total Depth (TD). This is further supported by the fact that the well is not producing, and interview findings indicate that it has been permanently plug and abandonment (P&A).

Table 3: Top 3 of the Lowest Drilling Cost in Indonesia.

No	Well Name	Well Depth (mMD)	Total Drilling Cost (USD)	Drilling Cost per meter (USD/m)	Well Status
1	Well O	~500	$1,709,100	~$3,430	Non-productive
2	Well P	~2000	$2,733,380	~$1,300	Productive
3	Well Q	~1300	$2,998,551	~$2,200	Non-productive

To understand the cost efficiency tips for the cheapest well, this study conducted interviews with related stakeholders involved in the drilling operation of Well P. From these interviews, it was found that this cost efficiency was achieved with several strategies as follows:

1. Long-term contracts and/or high quantities allowed for extensions without requiring a tender process. The high number of wells or extended contract durations incentivizes contractors to offer lower contract values.
2. Extensive and ongoing drilling campaigns mean that drilling services or rigs remain in the working area of the developer, reducing the costs associated with multiple mobilizations and demobilizations. While this lowers the total drilling cost, the cost per MW is higher due to more wells being required to achieve a certain electricity output, given the low success rate of drilling. As the drilling contractors drill more wells in the same area, they will accumulate lessons learned and leave the learning curve phase, ultimately leading to better performance and cost optimization.

3. The Developer owns and operates drilling rigs and several drilling services, including aerated drilling and cementing. Aerated drilling can be notably costly in Indonesia due to the scarcity of contractors, which allows them to dictate terms to geothermal developers.

However, these strategies may not necessarily be applicable to all developers, considering that each field has its own unique characteristics, and each developer has different operating strategies. Overall, this observation of the highest and lowest geothermal drilling cost data underscores the significant range in both expenses and outcomes associated with geothermal drilling in Indonesia.

6. CONCLUSION AND PATH FORWARD

The study reveals that geothermal drilling costs in Indonesia exhibit significant variability, ranging from 2 million to 29 million USD per well. This wide range underscores the diverse challenges and conditions encountered in geothermal drilling operations. High-cost outliers, such as the instances of wells costing up to 29 million USD per well, highlight specific challenges like incidents of stuck pipes, which can drastically increase costs. These findings point to the critical need for detailed analysis and effective management strategies to address these high-cost cases.

This study has also identified the components that contribute to 80% of the total drilling cost: rig, casing, directional drilling, fuel, and cementing. If this pattern of cost distribution persists across various geothermal drilling operations in Indonesia, it implies that drilling teams should prioritize the management of these principal service contracts, which account for the majority of the drilling costs. This approach suggests a strategic focus on key areas of expenditure rather than an equal distribution of resources and efforts across all contracts.

To further enhance the understanding and management of geothermal drilling costs in Indonesia, the following steps are recommended:

1. **Regular Updates to the Study**: Continuously update the study with new drilling data on an annual basis to capture trends and advancements in drilling technology. Regular updates will ensure that the analysis remains relevant and reflective of the current state of geothermal drilling in Indonesia.
2. **Enhanced Data Transparency and Sharing**: Encourage developers to disclose drilling cost data by addressing confidentiality concerns and demonstrating the collective benefits of data sharing for the industry. Promote the publication of comprehensive reports and studies on geothermal drilling costs to build a robust body of knowledge.
3. **Standardization of Reporting Requirements**: Collaborate with the Indonesian government to establish standardized reporting requirements for geothermal drilling activities. This will ensure consistency and completeness in the data collected, enhancing the reliability of the database.
4. **Development of a Geothermal Drilling Database**: Establish an integrated database for geothermal drilling costs in Indonesia. This database should include comprehensive data from all developers, ensuring that drilling engineers can access up-to-date information across the country. The database should standardize the collection and reporting of drilling cost components, facilitating accurate cost comparisons and benchmarking.

By implementing these steps, the geothermal industry in Indonesia can achieve greater cost efficiency and support the sustainable development of geothermal energy. The creation of an integrated database will play a crucial role in ensuring that drilling engineers can make better-informed decisions, ultimately contributing to the overall success and growth of the geothermal sector.

Proposing Corporate Work Plan and Budget (WP&B) Based on Risk Management to Ensure the Sustainability of Business Operations in the Kamojang Geothermal Area

Darussalam, Harahap. R., and Iman. A.S.

PT Pertamina Geothermal Energy Tbk

darussalam_1@pertamina.com, rahmad.h@pertamina.com, ahmad.iman@pertamina.com

Keywords: Work Plan and Budget (WP&B), Risk Management, Geothermal, Sustainability, Business Operations

ABSTRACT

The Kamojang Geothermal Area is an area that has been operating for quite a long time and continues to produce within the Kamojang-Darajat Geothermal Working Area (GWA). Kamojang Geothermal Power Plant (GPP) Unit 1, the first unit, began operations in 1983 and its production continuity has been maintained to this day. The sustainability of business operations needs to be supported by a comprehensive operation and maintenance budget. Every year, the operational and maintenance costs are proposed in the Work Plan and Budget (WP&B) Operating Cost Budget (OCB) submitted by the Kamojang Geothermal Area to the Head Office of PT Pertamina Geothermal Energy Tbk. To propose a comprehensive operation and maintenance budget, an appropriate basis is required as a reference. In this case, the Kamojang Geothermal Area will submit the WP&B OCB based on risk management so that the proposed budget truly aligns with the risk mitigation plan for the existing risks.

Risk management is an effort to manage risks based on the results of identifying potential hazards and everything that can impact a business operation. To address existing risks, mitigation is necessary to maintain the risks at a desired condition by reducing the level of residual risk from the inherent risk level. In determining the level of risk, a Risk Tolerance Limit (RTL) will be established and calculated based on the planned profit for the proposed WP&B year. The risk itself will be assessed based on the impact and probability of uncertainties that will affect business operations.

Considering the aging condition of assets and equipment in the Kamojang Geothermal Area, it is necessary to record potential risks based on the actual condition of these assets and equipment. The steps for proposing a risk-based WP&B include:

1. Risk identification (examining potential costs, accident history, and benchmarking similar equipment)
2. Calculating probability, impact, and risk weight
3. Recording the mitigation plan to be implemented and comprehensively calculating the mitigation costs
4. Determining the appropriate Cost Center/Work Breakdown Structure (WBS) and General Ledger (GL) account
5. Summarizing the WP&B OCB proposal based on risk management
6. Proposing and conducting a challenge session for the WP&B OCB with the Head Office of PT Pertamina Geothermal Energy Tbk

Therefore, it is expected that the proposed WP&B OCB will be a comprehensive risk management-based budget, and its use can be accounted for as a risk mitigation effort to ensure the sustainability of the Kamojang Geothermal Area business operations.

1. INTRODUCTION

The Kamojang Geothermal Area is one of the geothermal fields belonging to PT Pertamina Geothermal Energy Tbk and the first geothermal field to have been operating in Indonesia since 1983 when the first Kamojang Geothermal Power Plant (GPP) Unit 1 commenced operation. Nowadays, the Kamojang Geothermal Area has 5 (five) GPPs, with the latest unit commercialized in 2015 and a total installed capacity of around 235 MW.

The Kamojang Geothermal Area is an area that has been operating for quite a long time and continues to produce within the Kamojang-Darajat Geothermal Working Area (GWA). The sustainability of Kamojang Geothermal Area's business operations is about maintaining the reliability of its GPPs and production facilities. In order to keep the business operations running smoothly, the Kamojang Geothermal Area needs the Operating Cost Budget (OCB) to support the availability of tools, equipment, and services needed in operation and maintenance activities.

On the other hand, the sustainability of Kamojang Geothermal Area business operations should be ensured to meet the contracted production amounts for supplying steam and electricity to PLN as stated in the purchase agreement.

Figure 1: Kamojang Geothermal Power Plant.

2. METHOD

Every year, the operational and maintenance costs are proposed in the Work Plan and Budget (WP&B) Operating Cost Budget (OCB) submitted by the Kamojang Geothermal Area to the Head Office of PT Pertamina Geothermal Energy Tbk. To propose a comprehensive operation and maintenance budget, an appropriate basis is required as a reference. In this case, the Kamojang Geothermal Area will submit the WP&B OCB based on risk management so that the proposed budget truly aligns with the risk mitigation plan for the existing risks.

Risk management is an effort to manage risks based on the results of identifying potential hazards and everything that can impact a business operation. To address existing risks, mitigation is necessary to maintain the risks at a desired condition by reducing the level of residual risk from the inherent risk level. In determining the level of risk, a Risk Tolerance Limit (RTL) will be established and calculated based on the planned profit for the proposed WP&B year. The risk itself will be assessed based on the impact and probability of uncertainties that will affect business operations.

Considering the aging condition of assets and equipment in the Kamojang Geothermal Area, it is necessary to record potential risks based on the actual condition of these assets and equipment. The steps for proposing a risk-based WP&B include:

1. Risk identification (examining potential costs, accident history, and benchmarking similar equipment). For example, risk identification based on equipment failure is as follows:

Table 1: Historical Equipment Failure Data.

Date	GPP	Disturbance Status	Start Time	End Time	Duration (Hours)	Derating (Mw) (Based on URC)	Energy Lost (kWh)	Location	Cause	Remarks
02/10/21	Unit 5	FO1 (Forced Outage Immediate)	16:24	10:00	17.6	35.07	529,363.3	GPP	Main Steam System	Scrubber Leak
03/10/21	Unit 5	FO1 (Forced Outage Immediate)	10:00	10:00	24	35.07	841,566.7	GPP	Main Steam System	Scrubber Leak

2. Calculating probability, impact, and risk weight. Probability is measured by the criteria of frequency level. For the example above, the risk probability is “likely” or a score of 4 based on the company risk management guidance. Next, the impact is calculated in Table 2.

Table 2: Risk Event and Calculation of Its Impact.

7	**Unplanned Shutdown & Derating at GPP Unit 5**			
No	***Inherent Risk Financial Impact:***	***Value (Thousand USD)***	***Description***	
1	Loss Production Benchmark damage to Bottom Scrubber Unit-5 2021	>2000	30-day shutdown	
	Total Inherent Risk Financial Impact Value	**>2000**	**% Impact of Vavlue/RTL**	**Impact Score based on Impact Index (1= 0%-20%, 2=20%-40%, 3=40%-60%, 4=60%-80%, 5=80%-100%)**
			89.00%	5

After that, calculate the risk weighting as probability multiplied by impact, which equals 4 x 5 = 20, categorizing it as “high risk” based on the company's risk management guidance

3. Recording the mitigation plan to be implemented and comprehensively calculating the mitigation costs Calculate the mitigation costs to prevent the risk of Unplanned Shutdown & Derating events at GPP Unit 5

Table 3: Risk Mitigation Plan.

7	**Unplanned Shutdown & Derating at GPP Unit 5**		
No	***Risk Mitigation Plan:***	***Value (Thousand USD)***	***Description***
1	Maintenance costs, replacement of spare parts, repair of tools and equipment	>200	OCB for Non Rotating, Rotating, Instrument, and Electrical work centers

4. Determining the appropriate Cost Center/Work Breakdown Structure (WBS) and General Ledger (GL) account Based on the calculation of mitigation costs above, input and allocate those costs to the appropriate Cost Center/WBS and General Ledger (GL) account, for example:

Table 4: Cost Center and GL Account.

Cost Center	***Cost Center Description***	***GL Account***	***GL Account Description***	***Description in the WP&B OCB***	***Value (Thousand USD)***
C0121002	Maintenance KMJ - Joint Cost	6001013110	PLANT & MACHINERY MATERIAL & EQUIPMENT CONSUMED	OCB for Non Rotating, Rotating, Instrument, and Electrical work centers	>200

5. Summarizing the WP&B OCB proposal based on risk management. All calculations from the risk mitigation plan are then summarized on the worksheet of WP&B OCB
6. Proposing and conducting a challenge session for the WP&B OCB with the Head Office of PT Pertamina Geothermal Energy Tbk.

3. DISCUSSION

The relationship between the cost of risk mitigation and the comprehensive WP&B OCB submission is that the cost of risk mitigation provides a strong foundation for determining the budget required for business operations of Kamojang Geothermal Area. On the other hand, a good WP&B will be in line with the WP&B of the Directorate General of New, Renewable Energy, and Energy Conservation (NREEC), also known as the Rencana Kerja dan Anggaran Biaya (RKAB), which is mandatory to be submitted and approved by the Directorate General of New, Renewable Energy and Energy Conservation (NREEC), representing the Ministry of Energy and Mineral Resources (MEMR). By understanding and calculating the mitigation costs needed to reduce or avoid the impacts of potential risks, the Kamojang Geothermal Area can develop a more accurate and comprehensive budget. This enables Kamojang to allocate resources more effectively and minimize potential disruptions or additional costs that may arise from unexpected risk events.

Comprehensive WP&B submission based on the cost of risk mitigation is crucial in business operations for several key reasons:

1. Better Planning, by considering the costs of risk mitigation, companies can better plan for potential risks that may affect their projects or business operations. Resources can be allocated more strategically, ensuring that high-risk areas receive the necessary attention and funding.
2. More Effective Risk Management, identifying and evaluating mitigation costs helps in more effectively managing risks. This allows companies to anticipate potential issues and take necessary preventive or recovery measures. Risk management allows for proactive measures to be put in place, reducing the likelihood of risks materializing and impacting operations.
3. Financial Stability, including mitigation costs in the budget ensures that companies have adequate resources to handle potential risks. This helps maintain financial stability and reduces the risk of funding shortages during projects. Financial stability is maintained as resources are set aside to handle potential risks, preventing disruptions in operations.
4. Improved Decision-Making, a comprehensive budget submission based on mitigation costs provides a strong foundation for better decision-making. Management can prioritize projects with reasonable mitigation costs and avoid projects with uncontrolled risks. By showing that risks are managed proactively, the company can build trust with stakeholders, enhancing its reputation and credibility.

4. CONCLUSION

Proposing a Corporate Work Plan and Budget (WP&B) based on risk management involves integrating risk assessment and mitigation strategies into the financial and operational planning processes of a business is important. This approach ensures that potential risks are identified, evaluated, and addressed within the budget and work plan, leading to more resilient and sustainable business operations.

Therefore, it is expected that the proposed WP&B OCB will be a comprehensive risk management-based budget, and its use can be accounted for as a risk mitigation effort to ensure the sustainability of the Kamojang Geothermal Area business operations.

In summary, integrating the costs of risk mitigation into WP&B OCB submissions helps ensure that companies can manage their operations better, reduce uncertainty, and increase the likelihood of long-term success. This approach enhances planning, risk management, financial stability, decision-making, stakeholder confidence, and long-term sustainability, ultimately leading to more resilient and successful business operations.

ABSTRACT

Geothermal energy, recognized for its potential as a sustainable and low-emission power source poses a substantial environmental and social risks. Therefore, the importance of conducting comprehensive environmental and social impact assessment (ESIA) cannot be overstated. With the strategic importance of geothermal energy in supporting nationwide growth, it is imperative that good industry practice and internationally-compliant environmental and social impact assessment (ESIA) would need to be connected. The alignment and conduct of the local permitting requirements and the international ESIA standards can be challenging and consequently impede the process. However, there are only a few studies that examine procedural and process challenges for Indonesia and how these affect the ESIA process for geothermal projects. Drawing on the analysis of completed ESIAs and the semi-structured interview with stakeholders and ESIA experts, this paper identifies key challenges which include: (1) insufficient understanding of international standards and practice, (2) discrepancies between national and international requirements, (3) differences in risk appetite, and (4) challenges in integrating national and international assessment processes. The authors aim to raise awareness of these issues to foster improvements in ESIA practices in Indonesia and worldwide, especially concerning geothermal projects.

1. INTRODUCTION

Geothermal energy exploitations and productions present significant environmental and social risks and because they can alter the physical, biological, and social environments (Rahman et al., 2022). Therefore, the integration of environmental impact assessment and social impact assessment is crucially becoming part of project approval process (Dendena & Corsi, 2015; Ortiz et al., 2018) to prevent and/or mitigate negative environmental impacts, social conflicts, and financial losses. The concept and practice of ESIA are well-established and extensively developed at the international level (Glasson et al., 2019; Gulakov et al., 2020; Quigley, 2021), with agreed-upon values, principles, and guidelines for implementation (Asian Development Bank, 2009; International Finance Corporation, 2012a; International Union for Conservation of Nature, 2020; Vanclay et al., 2015). ESIA is widely used by private lending institutions that adhere to the Equator Principles, multilateral development banks, and other international financial institution (Corsi et al., 2015; Dendena & Corsi, 2015; Romianingsih et al., 2023; Vanclay, 2020).

Romianingsih et al. (2023) have studied the discrepancies between ESIA based on international standards and *Analisis Mengenai Dampak Lingkungan* (Indonesia Environmental Impact Assessment or Amdal) which follows national regulations. This issue is common in developing countries and countries in transition (Gulakov & Vanclay, 2018; Omenge et al., 2020). However, the article is fully based on document analysis, excluding the perspective of the key stakeholders. This proceeding paper aims to address the gaps by exploring the challenges of implementing international ESIA standards in Indonesia, particularly for geothermal projects, through document analysis and semi-structure interviews with key stakeholders and leading ESIA experts in Indonesia.

2. LITERATURE REVIEW

2.1 ESIA versus Amdal

Environmental Impact Assessment (EIA) is a systematic, holistic, and multidisciplinary process used to identify and evaluate the potential environmental consequences of proposed development plans, thereby facilitating informed decision-making and sound environmental management (Glasson et al., 2019; Loomis & Dziedzic, 2018; Roos et al., 2020). The EIA (called Amdal in Indonesia) was formally introduced in Indonesia in 1982 through the enactment of Law No. 4 of 1982 on Basic Provisions for Environmental Management. However, its implementation was initially limited due to the lack of detailed guidelines and the limited understanding of key stakeholders. During this period, some Amdal studies were conducted to meet foreign aid requirements and donor agency requests (Purnama, 2014). It was not until 1986, with the enforcement of Government Regulation No. 29

of 1986 on Environmental Impact Analysis, that EIA began to be systematically and extensively implemented (Purnama, 2014).

Social impact assessment (SIA), health impact assessment (HIA), and strategic environmental assessment (SEA) have also developed under the umbrella of the EIA due to dissatisfaction with previous assessments that had been implemented (Hacking, 2019; Harris et al., 2018; Vanclay, 2020). A growing body of literature has been published on Amdal in the past five years which criticize the weakness of regulatory enforcement of Amdal. The regulation is supposedly weak with ineffective penalties for non-compliance (Zahroh & Najicha, 2022), the lack of accountability of public participation process (Kurniawan et al., 2020; Lai & Hamilton, 2021), and the absence of climate change discussion, biodiversity offset, and analysis of alternative (Swangjang, 2018). These feedback and evaluation would justify the requirement for ESIA which follow the international standards to close those gaps identified in Amdal. ESIA provides a more comprehensive approach for integrated assessments that encompasses evaluation of the biophysical and social impacts of projects, programs, and policy initiatives (Dendena & Corsi, 2015).

The commitment of financial institutions to adopt voluntary regulations aims to ensure their activities contribute positively to sustainable development (Contreras et al., 2019). In the last decade, development projects funded by international institutions have been required to meet environmental and social standards established by these institutions while also complying with Indonesia's national regulations and standards. These environmental and social safeguards form the foundation for the formulation of Environmental and Social Impact Assessments (ESIA).

2.2 International Standards for ESIA

Geothermal projects in Indonesia heavily involve foreign investors due to their substantial investment requirements (Chelminski, 2022; Rakhmah, 2023). This trend reflects developed countries' commitment to supporting developing nations in transitioning to renewable energy sources (Mori, 2020). It has become standard practice for project developers to prepare ESIA as a prerequisite for securing loans from international financial institutions. Depending on the preferences of the lenders or donors involved, one or more of the followings would typically be applicable in Indonesia:

a. International Finance Corporation Performance Standards on Environmental and Social Sustainability (IFC PS);
b. Asian Development Bank Safeguard Policy Statement (ADB SPS);
c. Guidelines for Confirmation of Environmental and Social Considerations by Japan Bank for International Cooperation (JBIC);
d. Equator Principles 4 (EP4); and
e. The World Bank Environmental and Social Framework. (World Bank ESF) including the World Bank Group Environmental, Health, and Safety (EHS) Guidelines for Geothermal Power Generation

The aforementioned detail the requirements for the preparation of ESIA documents which the project sponsor shall adhere to in order to ensure environmental and social aspects are addressed with the process, including meaningful public participation, assessment and management of projects impacts across its project phases. Among these standards, the IFC PS often serves as primary benchmark. While internationally recognized, the Principles and Guidelines on Business and Human Rights have seen limited reference in Indonesia thus far (Götzmann et al., 2016). The IFC Performance Standards ensure comprehensive consideration of labor and working conditions (PS2); resource efficiency and pollution prevention (PS3); community health, safety, and security (PS4); involuntary resettlement (PS5); biodiversity conservation (PS6); indigenous peoples (PS7); and cultural heritage (PS8). These are generally in alignment with all 17 United Nations Sustainable Development Goals (UN SDGs). Emphasis must be placed on addressing the needs and aspirations of vulnerable communities. The IFC Performance Standards also provide definitions for project area of influence (AOI), associated facilities, and cumulative effects (International Finance Corporation, 2012a). After conducting the impact assessments, project proponents are required to establish ongoing monitoring processes and effective systems for managing social and environmental impacts for the whole lifecycle of the project.

3. METHODOLOGY

The methodology from Gulakov et al. (2020) was adapted for this study with minor modifications. This paper primarily analyzed two completed geothermal ESIAs in Indonesia as case studies. As part of triangulation to mitigate potential bias, the study also incorporated semi-structured interviews with nine stakeholders (as presented on Table 2) and two ESIA experts based in Indonesia All interviews were conducted in accordance with social research ethics (Vanclay et al., 2013), with each interviewee signing a consent form prior to participation. Table 2 presents the breakdown of the interviewees based on their role and/or institution.

Table 1: SDG Mapping of IFC Performance Standards (International Finance Corporation, 2023).

IFC Performance Standards	SDG Alignment
Performance Standards 1 Assessment and Management of Environmental and Social Risks and Impacts	
Performance Standards 2 Labor and Working Conditions	
Performance Standards 3 Resource Efficiency and Pollution Prevention	
Performance Standards 4 Community Health, Safety, and Security	
Performance Standards 5 Land Acquisition and Involuntary Resettlement	
Performance Standards 6 Biodiversity Conservation and Sustainable Management of Living Natural Resources	
Performance Standards 7 Indigenous Peoples	
Performance Standards 8 Cultural Heritage	

Table 2: List of Interviewees.

Institution/Role	Number of Interviewees
Project sponsors (private corporations)	2
Ministry of Environment and Forestry	1
Local Environmental Agency	1
Financial institutions	2
Consultants	2
Academia	1
ESIA experts based in Indonesia	2

The discrepancy between procedural features of Amdal and ESIA as well as national requirements and international requirements for impact assessment formed the basis of the interviews with the stakeholders and experts. These interviews were conducted either in person or via MS Teams or Zoom between January and April 2023. The language of the interviews, Indonesian or English, was chosen based on the preference of the interviewees. Each interview lasted between 60 to 90 minutes, and interviewees were informed in advance about the topics and the outline of the questions. Following the interviews, the authors employed simple coding techniques to analyze the qualitative data, aiming to capture the key themes and synthesize the overall findings from the interviews.

4. RESULTS AND DISCUSSION

Based on the document analysis and interviews, four key challenges were identified: (1) insufficient understanding of international standards and practice, (2) discrepancies between national and international requirements, (3) difference in risk appetite, and (4) challenges in integrating national and international assessment processes.

4.1 Insufficient understanding of international standards and practice

Typically, in Indonesia, performance standards and requirements are perceived as regulations to be complied by a project. The specificcompliance requirements are presented in a checklist and/or template that a project must accomplish. This approach is shaped by the conventional nature of Amdal requirements. Similar to an ESIA screening and scoping, the local Amdal process is initiated by a screening process that identifies the project type, compliance requirements, and reporting threshold set in the regulations. Should the project exceed a certain threshold, usually for environmentally critical projects, an EIA becomes mandatory. Another example is Government Regulation No. 22 of 2021 and its appendices that specify the stakeholders to be engaged, procedures for public disclosure of the project, the template for Amdal document, among others. These guidelines are highly

detailed and straightforward, making them easy to follow, but they also indirectly suggest that anything beyond the prescribed requirements is excessive and unnecessary, thus discouraging the adoption of best practices during the impact assessment process.

Geothermal companies, familiar with these national requirements and experienced in their application, often adopt an Amdal approach to ESIA. However, such approach is fundamentally flawed when applied to international standards, as it contradicts their intended purpose. Unlike prescriptive national regulations, international standards offer a framework for managing potential social impacts of a project. They do not provide the same threshold screening requirements as local Amdal but require the project developer to screen the project with defining project magnitude, boundary, emissions, and scientific rationale which are often beyond the requirements and review scope of the local ministry. Other challenges include the lack of alignment between Amdal and ESIA on stakeholder engagements wherein the international requirement is vaguer on procedural steps but does require comprehensive stakeholder identification and consultations. It is up to the project proponent and their consultants to choose and adapt methods for effective information sharing and engagement. Four interviewees noted that international standards focus on principles, while Indonesian requirements specify detailed processes and template. Overemphasis on detailed national regulations can cause company personnel to focus on ticking the box and meeting the minimum requirement, hence, losing sight of the broader objectives (Gulakov et al., 2020).

However, one interviewee raise a contradictive opinion: the lack of understanding and limited practical application of international standards in Indonesia can be attributed to the disconnect between these global frameworks and the local context. While the principles underlying these standards are universally applicable, their implementation requires a nuanced understanding of the unique cultural, political, and socioeconomic factors that shape the Indonesian business landscape. For example, the flexibility inherent in the non-prescriptive nature of the IFC Performance Standards and the ADB Safeguard Policy Statement can be both a strength and a challenge. This flexibility allows for the tailoring of the standards to local needs, but many studies suggest that it also creates ambiguity that can be exploited by companies seeking to minimize their compliance efforts (ADB, 2014; Cahyandito & Pau, 2017; Thanh et al., 2020).

It is also observed from interviews that smaller companies in particular often struggle to understand the nuances and practical applications of international standards while multinational enterprises operating in Indonesia recognized the importance of these international standards and platforms in informing their scoping practices. This is consistent with what has been studied by Borgert et. al. (2018) but the recognition did not necessarily translate to a deep understanding or consistent application of the requirements.

This lack of understanding, coupled with the time and budget constraints faced by project sponsors, has led to a tendency to prioritize speed over the comprehensive analysis necessary for a meaningful impact assessment. The rush to complete the assessment process, driven by these external pressures, often compromises the integrity of the findings and the ability to effectively address potential environmental, social, and economic implications.

4.2 Discrepancies between national and international requirements

Project developers must comply with national laws when planning for geothermal projects. If they are seeking international funding, they must also adhere to the IFC PS requirements (International Finance Corporation, 2012a). However, the document analysis and the interviews identified discrepancies between national law and the IFC requirements. One of the primary differences lie in the stakeholder engagement procedures. IFC PS and ADB SPS mandate meaningful public consultation, requiring project developers to actively seek input from affected communities, including marginalized or vulnerable groups. However, the national regulations in Indonesia are not as comprehensive as international standards, leading to limitation in the depth and breadth of stakeholder engagement. For instance, indigenous communities in Indonesia are not always clearly defined, and the recognition of their rights and the need for their free, prior, and informed consent (FPIC) is not consistently applied across all geothermal projects. This can create issues between the project developers' obligations under national standards and their ability to comply with international standards, potentially leading to conflicts.

Another area of divergence relates to the definitions and thresholds used in assessing environmental and social impacts. International frameworks often have more comprehensive and stringent criteria for determining the significance of impacts, such as the IFC's requirements around the assessment of ecosystem services (Borgert et al., 2018). In contrast, Indonesian regulations may rely on less rigorous impact assessment methodologies, leading to discrepancies in the identification and mitigation of potential adverse effects (Borgert et al., 2018). The treatment of ecosystem services for the local impact assessment often miss the key assessment and mitigations for biodiversity values critical for livelihood, natural capital, and climate resilience. Additionally, the local definition of “critical habitat” is limited to the definition from national legislation which significantly differs from international guidance documents that include ecologically sensitive areas, key biodiversity areas, and others resulting in the underestimation or overlooking of sensitive ecological areas that warrant special protection measures (Semedi et al., 2017).

This disconnect between international and national standards can also manifest in the approach to managing resettlement and livelihood restoration. While international guidelines emphasize the need for comprehensive compensation, support for livelihood restoration, and the prevention of impoverishment, national regulations in Indonesia may not always mandate such comprehensive measures, potentially leaving affected communities inadequately supported (Borgert et al., 2018). Moreover, international guidance notes (International Finance Corporation, 2012b) recognize the rights of informal settlers and stakeholders without formal proof of authority/ownership of land and assets while the local regulations often do not consider these for compensation.

In terms of indigenous peoples and indigenous cultural communities, the lack of a clear and unified definition of "indigenous peoples" in the Indonesian context can create ambiguity and a failure to recognize the unique rights and needs of these communities, which are often central to international standards (Ferrol-Schulte et al., 2015). This can lead to the exclusion of important stakeholders from

the consultation and decision-making processes, potentially exacerbating existing vulnerabilities and tensions. The international standards, such as the IFC Performance Standards, require a more rigorous assessment of the environmental and social impacts, as well as stronger protections for indigenous rights and community livelihoods. However, the national regulations may not have provided sufficient safeguards, leading to conflicts between the project developers' obligations and their ability to comply with local requirements. This disconnect can undermine the intended benefits and leave affected communities insufficiently supported.

The other key difference is in the determination of project area of influence (AOI). International standards mandate that the ESIA takes into account the impacts of associated facilities, whereas Indonesian regulations do not. Associated facilities are described as “facilities that are not funded as part of the project and that would not have been constructed or expanded if the project did not exist, and without which the project would not be viable” (International Finance Corporation, 2012). Examples of such facilities often include pipelines, utilities, warehouses, and logistics terminals. Moreover, Amdal process has primarily concerned with the direct, immediate effects of a project on surrounding environment and communities while ESIA process emphasizes the ongoing management and monitoring of environmental and social impacts throughout a project's lifecycle, with a stronger emphasis on overall positive outcomes and community engagement (Vanclay, 2020). Additionally, under international performance standards, the AOI may be amended or expanded based on the verification and magnitude of impacts during project construction and operations based on results of modeling exercises (e.g., air dispersion, thermal plume, etc). The local regulation definition of AOI remains constant throughout project implementation.

4.3 Differences in risk appetite

The interviewees from financial intuitions and the ESIA experts stressed that there are the differing risk appetites between the government as the reviewer and approver of Amdal, and the financial institutions as the reviewer and approver of ESIA. Amdal embodies the project's environmental management, whereas ESIA serves as risk management documentation mandated by lenders. The government, as the entity responsible for the overall development and economic growth of the country, often has a higher risk tolerance when it comes to environmental and social impacts, as they may prioritize economic considerations over strict environmental and social safeguards. This can lead to the approval of projects with relatively higher environmental and social risks, as long as they are deemed economically beneficial for the country.

In contrast, financial institutions, particularly those that have adopted the IFC Performance Standards, have a low-risk appetite when it comes to environmental and social impacts. These institutions are primarily concerned with the financial and reputational risks associated with financing projects with significant environmental and social risks, and they are often more stringent in their evaluation and approval of projects. This difference in risk appetite can result in situations where a project that has been approved by the government under the Amdal process may not meet the requirements set forth by the international standards.

4.4 Challenges in integrating Amdal and ESIA processes

When a project is in its early stages and the proponent seeks international financing, both Amdal and ESIA are generally required. This raises the question of whether these two processes can be combined as the timeline for execution and approvals for Amdal impact the ESIA schedule and would have schedule and commercial effects to the proponent’s project Are their differences so substantial that they should be performed separately or in parallel rather than as a combined process?

While both assessment frameworks aim to ensure environmental and social sustainability, their differences in principles, requirements, reporting formats, and decision-making processes present significant challenges for integration. As one interviewee noted, some consultants have attempted to combine them, but often decide later that keeping them separate is more practical. The complexity of merging the two processes necessitates that project developers invest considerable time and resources in collecting, analyzing, and presenting data to meet both

national and international standards. This can lead to delays, increased costs, and potential conflicts among stakeholders.

To simplify the process, the case study projects completed the Amdal according to national requirements and then prepare a Supplementary ESIA to address issues not covered by Amdal, such as labor conditions, livelihood restoration, involuntary resettlement, biodiversity, cultural heritage, indigenous peoples, and cumulative impacts. Further, to save time and budget during the early stages of a project, project sponsors and consultants usually map the differing national and international requirements and develop a strategy for conducting stakeholder engagement of Amdal and ESIA as a joint process. The same approach applies to baseline studies. Efforts must be made to ensure these studies meet both national and international standards. It is noteworthy that representatives from the case study company are cooperative and hence made this approach doable. However, if company staffs are not cooperative or do not understand the need for more extensive ESIA consultations, it is advisable to conduct EIA and ESIA stakeholder engagement and baseline studies in parallel.

5. CONCLUSION

Implementing international standards for impact assessment in Indonesia is typically challenging. A significant issue arises from the differences between the requirements of Amdal and international ESIA procedures. It can be problematic when company personnel accustomed to the national EIA framework apply the same approach to the international ESIA process. Since the results of Amdal and ESIA undergo different review processes with varying risk appetites, combining them is difficult. The most practical and pragmatic approach is to complete Amdal according to national requirements and then prepare a Supplementary ESIA to address any issues not covered by Amdal.

Addressing these challenges requires a multi-pronged approach. Strengthening the regulatory framework for environmental and social impact assessment, while also enhancing stakeholder engagement and awareness, can help bridge the gap between theory and practice. Investing in capacity-building initiatives that enhance the project sponsors' understanding of the assessment process and the importance of adhering to global best practices. This may involve targeted training programs, knowledge-sharing workshops, and the establishment of collaborative networks that facilitate the exchange of expertise and lessons learned across geothermal projects. Additionally, project sponsors must be willing to allocate adequate resources, both in terms of time and funding, to support a thorough and rigorous impact assessment process that aligns with international norms and requirements.

ACKNOWLEDGEMENT

We extend our appreciation to the representatives of the case study projects and all interviewees for their cooperation during the data collection. We thank Ardi Hartanto, Claire Aitkenhead, and Katherine Gavile for their constructive feedback on this paper.

Keywords: Keystone Species, Wildlife, Coexistence, Geothermal Power Plant, Eco-Friendly

ABSTRACT

Human activity is inevitably impacting the environment in every environment component including air, water and soil which potentially affect biodiversity. Considered as renewable and eco-friendly, geothermal power plant would still potentially impact the environment including the biodiversity that lives in it. The objective of this paper is to study whether the wildlife could possibly coexist with Darajat Geothermal Power Plant which is located within Taman Wisata Alam Gunung Papandayan (Nature Park), Garut Regency, West Java, Indonesia. The objects for this study are the keystone species at Gunung Papandayan Nature Park which is Javan leopard (Panthera pardus melas). Javan leopard is reported to be elusive and rarely seen near the power plant. To confirm the existence of Javan leopard near Darajat Geothermal Power Plant facilities, Star Energy Geothermal Darajat II, Limited (SEGD) initiated wildlife monitoring around the facilities with cruising method and camera traps. The result of this study shows that Javan leopard was able to adapt and uses geothermal facilities such as steam pipeline inspection pathway, inactive well pad and roads. This study indicates that the keystone species at Gunung Papandayan Nature Park can adapt and coexist with Darajat Geothermal Power Plant.

1. INTRODUCTION

The trends of increasing temperature due to global warming are keep growing up. The main cause of global warming is the emission of greenhouse gasses produced by anthropogenic activities specifically activity that uses huge amount of fossil fuel (Mukhopadhyay, 2013). Therefore, the development of renewable energy has become global concern. Geothermal power is a renewable energy resource that has attracted significant and continued investment with a forecasted growth of 28% power generation capacity (approx. 4GW) between 2018 and 2023 (IEA, 2018; Ng et al., 2021). However, increases in renewable energy infrastructure can also be associated with negative impacts on habitats and species (Ng et al., 2021). There is a numerous overlap between renewable energy facilities and important conservation areas that potentially compromise the goals of biodiversity conservation (Rehbein et al, 2020).

In this modern era, it is more difficult to maintain biodiversity and function of forests. This is caused by the increasing needs of humans require more land for production. In fact, forests have various functions both directly and indirectly utilized. Some functions that usually getting overlooked are weather control, carbon storage, water storage and aesthetic functions (Pearce,2017). These functions do not directly impact the economy of the community, but their absence will affect human life in general.

Indonesia is a mega biodiversity country, blessed with abundant geothermal energy potential. With great potential to utilize renewable geothermal energy there is also potential threat of negative impact on biodiversity. A geothermal power plant in Darajat as an example is located at Gunung Papandayan Nature Park area that has high biodiversity. The latest research suggests that at least 101 species of birds, 15 species of herpetofauna and 24 species of mammals including endangered species such as Javan surili, dhole and Javan leopard found in this area (Junaid and Fariz, 2021). Biodiversity is a comprehensive umbrella term for the extent of nature's variety or variation within the natural system; both in number and frequency. Biodiversity exists as a complex web of life forms that interact with each other in an ecosystem, in a region or globally. Biodiversity drives the functioning of ecosystems through countless reciprocal interactions with the physical and chemical components of the environment (The Royal Society, 2003). Humans' activity near wildlife habitat will likely trigger a conflict between them.

Animals with remarkable adaptation ability might be able coexist with humans despite the rapid changes in their habitat. Coexistence is defined as a dynamic but sustainable state in which humans and wildlife co-adapt to living in shared landscapes, where human interactions with wildlife are governed by effective institutions that ensure long-term wildlife population persistence, social legitimacy, and tolerable levels of risk (Mekonen, 2020). The survival of the keystone species is the most important among the other species. Keystone species are those whose

existence affects the ecosystem (Payton et al., 2002). They include organisms that control potential dominants, provide critical resources, act as mutualists and act as ecosystem engineers. The absence of the keystone species may trigger the ecosystem to collapse.

The goal of this paper is to study the possibility of sensitive keystone species to coexist with geothermal power plant facility. This paper will represent how geothermal activity could potentially impact wildlife which later can be used to develop conservation plan to manage the potential impact. The subject of this research is Javan leopard (*Panthera pardus melas*). Javan leopard act as top predator to control the population of its prey and stabilize the ecosystem.

2. METHOD

2.1 Study Site

Research was conducted from 22 February 2022 to 27 February 2024 in a Darajat Geothermal Power Plant located in Pasirwangi Village, Garut, West Java, Indonesia (coordinate 07°11'09"- 07°15'40"S and 107°41'54"-107°45'40"E). Darajat Power Plant is located within Taman Wisata Alam (Nature Park), Hutan Lindung (Protected Forest) and private land around 1740-2200 above sea level in a valley near Mount Kendang which is part of Papandayan Mountains. The location study is narrowed to Nature Park area around geothermal facilities such as well pads, steam pipeline and biodiversity essential area (e.g., water hole).

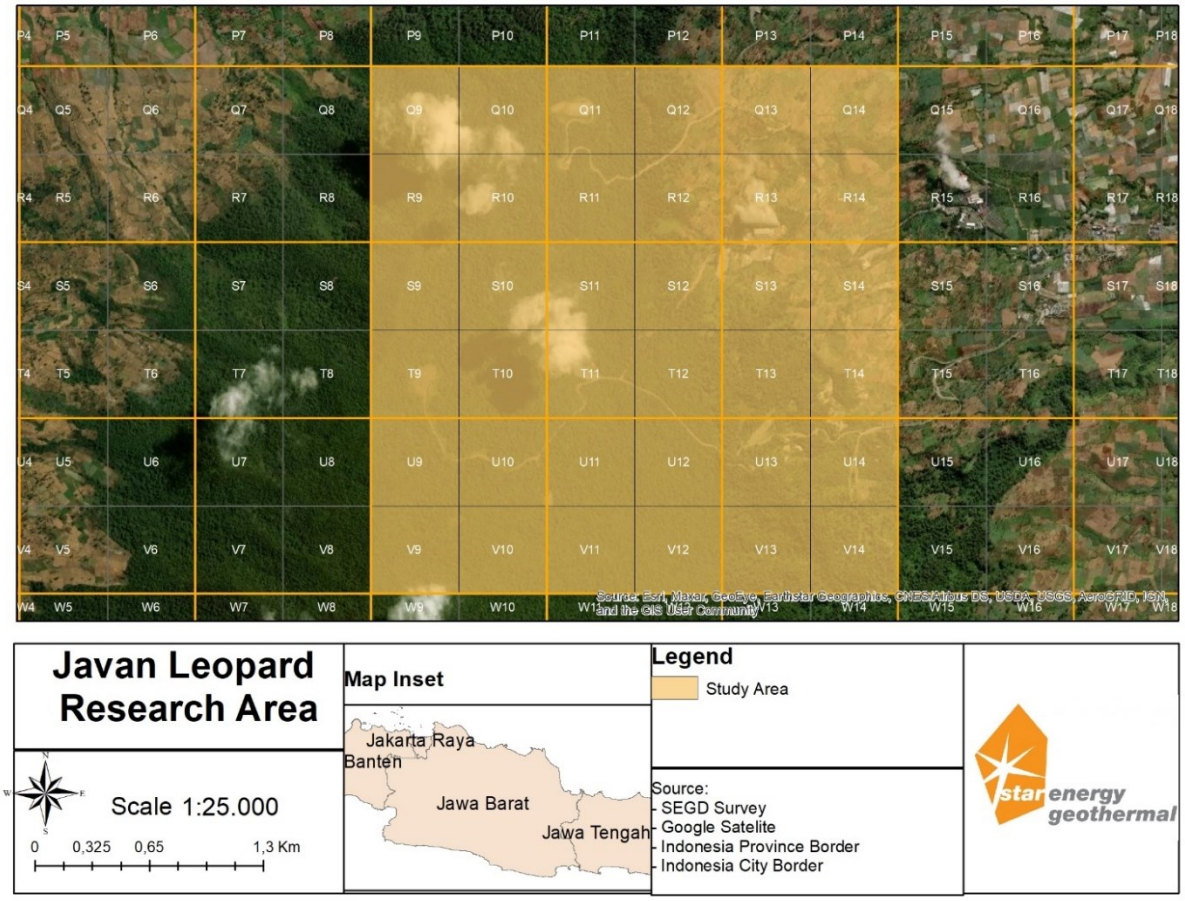

Figure 1: Study location map.

2.2 Procedure

Research Data were collected through direct and indirect data collection methodology. Direct data were collected using Visual Encounter Survey (VES) method and camera traps installation. VES data collected by cruising through footpath available at the area (large mammals will be more likely to use these footpath). Indirect data such as carcasses, footprints, feces, claw marks and other sign that prove the existence of Javan leopard were recorded simultaneously with VES method. Javan leopard footprints were identified referring to a guidebook (Van Strien, 1983). Camera traps were installed using line transect method, measuring about 1 kilometre in length. 2 camera traps were installed in each transect. The distance between camera depends on the observation of Javan leopard signs and their potential tracks in the area. Camera traps installation location were based on signs found in the area. Total of six camera traps were being used in the study, and all cameras are set to record video. The

camera surveillance period was set for three month per location and being checked monthly for maintenance and data collection. Camera traps were installed near a track that potentially used by wildlife. Camera traps were mounted on a tree 15-30 cm above the ground depending on the contour of the installation location and camera properties (Molloy, 2018). Field guide is used as a reference to identify species of animals observed or their existence signs (Shepherd & Shepherd 2018).

Due to the increase in the spread of covid-19 cases, data collection was carried out by following the covid-19 protocol issued by the Indonesian government and the Star Energy Geothermal Darajat company. Before conducting the study, all participants were required to take an antigen test. The number of participants was also limited to the minimum. After all participant candidates are declared covid-free, the research is carried out. During the research, contact between participants was limited to a minimum and risky contact such us borrowing cutlery was not allowed. The camera traps method makes it possible for this research to be held for a long period of time with less contact of the researcher team.

2.3 Data Analysis

2.3.1 Number of individuals

The Javan leopard number of individuals is calculated by identifying Javan leopard recorded by camera traps. Face and flank spot pattern were used to identify the individual. Individual's gender was identified from their physical appearances. The home range size of Javan leopard and physical barrier were also considered (e.g., farmland, cliff, roads) to determine the individual.

2.3.1 Encounter rate

The data were analysed by estimating encounter rate of the species. Encounter rate was calculated by dividing number of captured pictures of Javan leopard with total days the cameras were active, multiplied by 100 (O'Brien et al. 2003; Shahida et al. 2018). Encounter were considered distinct events if occurred more than 30 minutes apart or if the next encounter is different individual.

3. RESULT AND DISCUSSION

Camera traps data collection was conducted from February 2022 to February 2024 and successfully identified 9 Javan leopards. The leopards were recorded 131 times during the research. The population are consisted of two adult males, four adult females, one juvenile and two cubs. Some leopards were interested in camera traps that they tried to sniff them especially when the camera traps were just installed or getting moved to other location. Their curiosity made it possible for the camera to capture spot pattern of their faces and flanks. This facial and body spot features was used to identify each of Javan leopard individuals. Javan leopard population is shown in table 1.

Javan leopards were captured at several locations around Geothermal field site.Within the observation area, there are several signs that indicate leopard's existence such as feces, footprints, and claw marks. These signs show that leopards were passing these locations frequently. There are nine individuals captured by camera traps.

Table 1: Leopard's population structure.

Individuals	Age Class	Sex
Leopard A	Adult	Female
Leopard B	Adult	Female
Leopard C	Adult	Male
Leopard D	Adult	Male
Leopard E	Adult	Female
Leopard F	Juvenile	Not identified
Leopard G	Adult	Female
Leopard H	Cubs	Not identified
Leopard I	Cubs	Not identified

One of the most frequently used pathways is a path near well pad W1 and well pad SF. There was several individual that uses this path but the most often is leopard D. Leopard D is considered an alpha male in the area due to his wide range of area in Darajat geothermal field site and frequent record. Several female individuals also sighted using this track which is overlapping of female's and male's home range is common in leopard (Snider et al., 2021, Muller et al., 2022). This track is located in the far end of geothermal field site, making this location is rarely visited. Although there are signs that showing these track is often used by animals and human. These condition makes this location a suitable track for Javan leopard since they prefer a spacious footpath rather than vegetation dense track.

SEGD archives show that leopard monitoring has been conducted in Darajat geothermal field site. In the biodiversity report, it was noted that in 2016 four leopard individuals were found in Darajat Geothermal field site. A total of four leopard individuals were found again in 2022. In 2022, SEGD began to conduct routine and intensive biodiversity monitoring. In 2023, two new adults and one juvenile were identified. two cubs were found, bringing the total number of new individuals to nine in 2024. This finding is a good sign that the javan leopards population is regenerating.

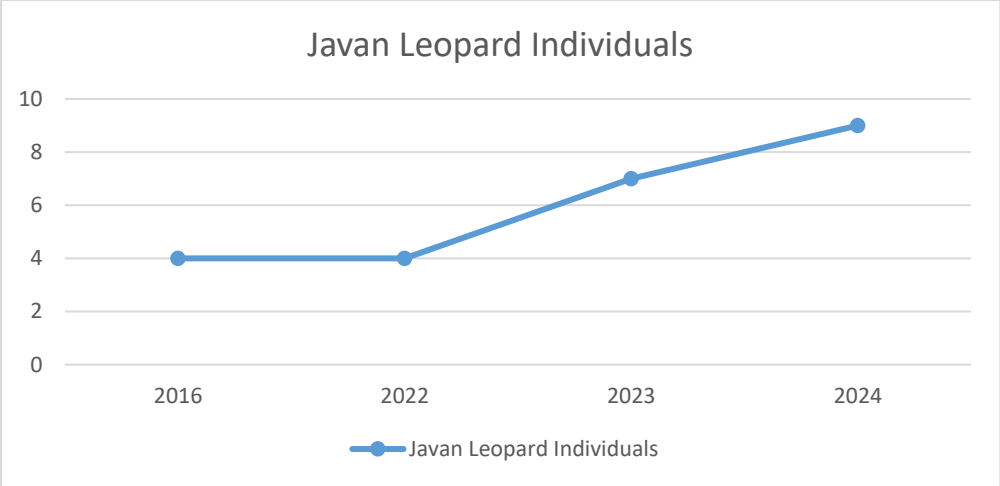

Figure 2: Leopard encounter rate.

Encounter rate analysis shows that javan leopard in Darajat has ER value of 17,8%. Camera traps were able to capture 131 picture based on 735 trap days. W1 & SF site is the most visited site among the site sampling areas. According to the encounter rate of each individual Leopard D has the highest encounter rate which indicate that Darajat geothermal field site is indeed its homerange area and possibly its core area. Core area is an area which is used more often than the rest of the homerange area and it is morelikely is an area that used to sleep/rest, find shelter and an area with abundant food sources (Burt, 1943). Leopard C has the second highest encounter rate. Though Leopard C's encounter keeps getting lower each year. It is possible that Leopard C was a young male adult looking for its own teritory. It's possible that it has already established its own homerange making his appeareance getting rare.

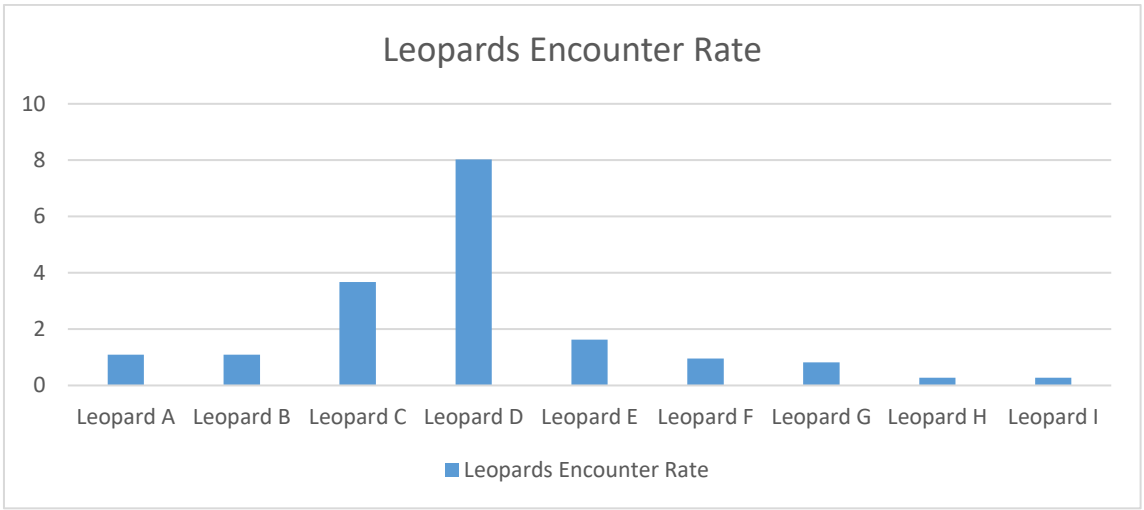

Figure 3: Leopard's encounter frequency.

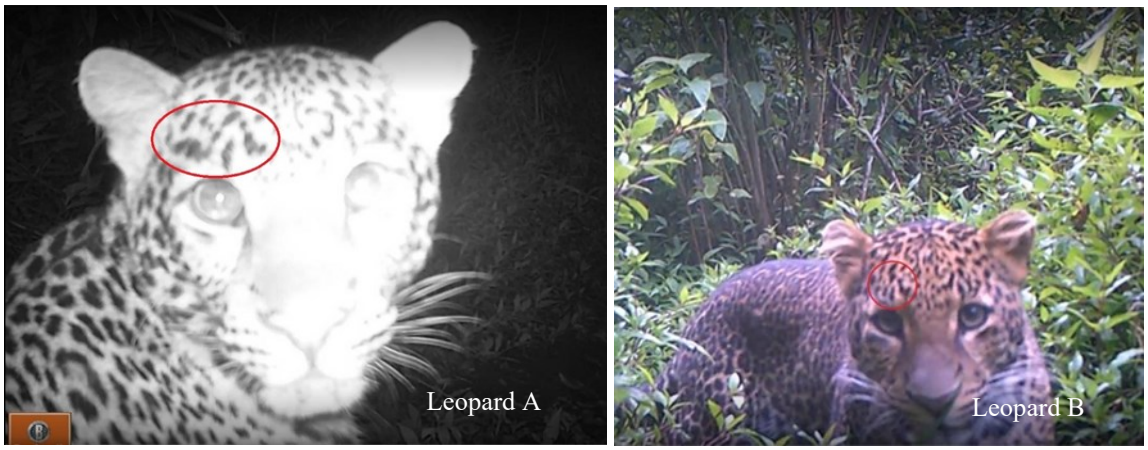
Javan leopard captured in relatively remote area and far from humans activity. Geothermal steam extraction operation most of the time operate automatically. The company staff only visit wellpad and steampipe once in a while for inspection and maintenance. Wellpad area will be busy and produce high intensity noises only when there is a drilling project or a maintenance program. For example the data collected from SF wellpad. Camera traps were installed near drilling activity project area for two months but no animals passes by the area. Only small mammals such as tree shrew and birds were captured. It is most likely due to disturbance caused by well drilling process conducted in wellpad SF. Seeing how geothermal production works with its low maintenance and low humans activity it seems javan leopard was able to adapt and live alongside geothermal company activity.

Figure 4: Example of javan leopard sign.



Javan leopards can adapt and live near a geothermal powerplant is because the area is a habitat for its potential prey. There are at least 18 identified potential prey found near geothermal activity. The abundance of prey species allows the javan leopard to survive. The primary prey for javan leopard is ungulates and primates (Gunawan et al., 2012). Primates such as javan surili (Presbytis comata) and ebony leaf monkey (Trachypithecus auratus) are frequently seen in various location near geothermal facilities.

Table 2: Potential prey.

No	Family	Latin Name	Local name
1.	Bovidae	Bubalus bubalis	Water Buffalo
2.	Canidae	Canis lupus familiaris	Domesticated dog
3.	Cercopithecidae	Presbytis comata	Javan surili

22.	Sciuridae	Petaurista petaurista	Red giant flying squirrel

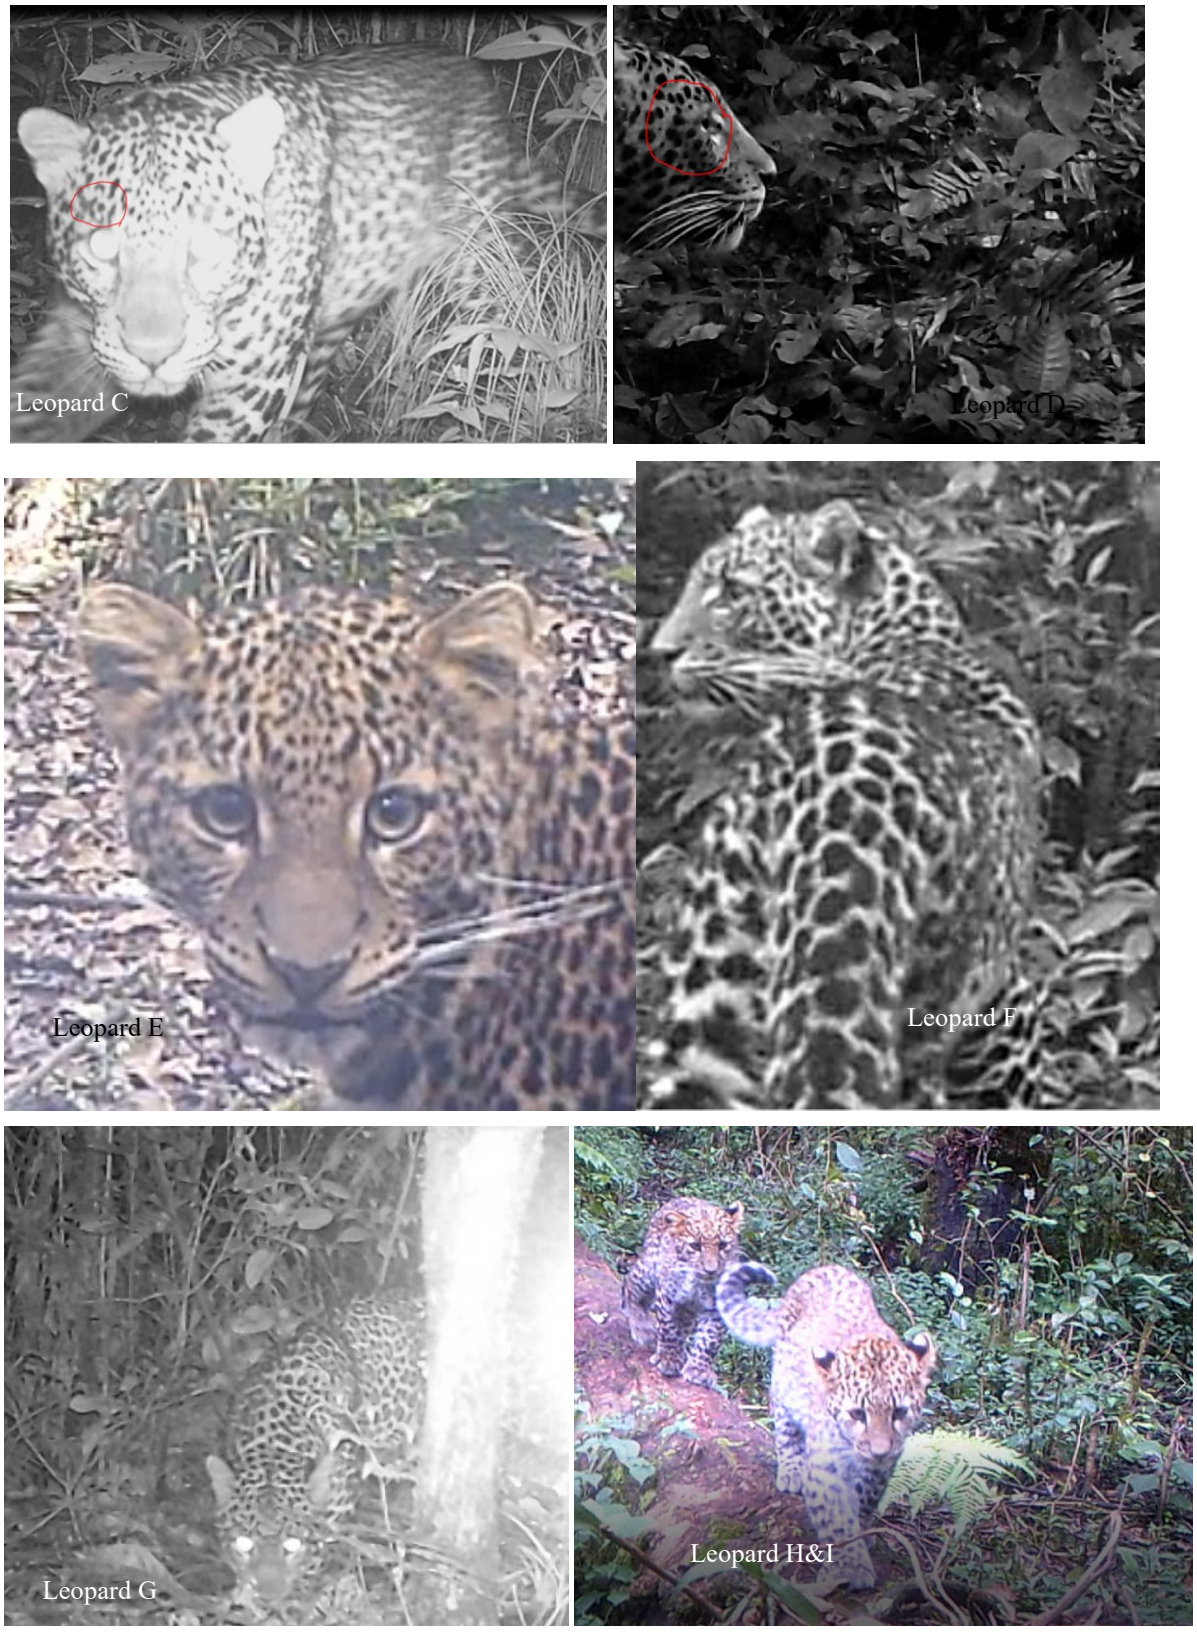

Figure 5: Leopard facial spot.

Potential prey species in Darajat mostly from family Mustelidae. Overall leopard species prefer to hunt large prey weighting 10-40 kg (Hayward et al., 2006). In Darajat the only prey that fits into this category is wild boar and barking deer. When these prey is hard to find or in difficult times Javan leopard may depend heavily on locally abundant small prey which is abundant in Darajat. Abundant prey option species in Darajat is one of the reasons javan leopard succeeded to adapt in geothermal project area.

4. CONCLUSION

Javan leopard as one of the keystone species within Papandayan Nature Park is proven to be able to coexist with Darajat Geothermal operation. They can adapt to various type of land including brushwood, natural forest, forest patch around geothermal power plant facilities such as well pad and steam pipeline. The reason Javan leopard was able to adapt in geothermal site is the nature of geothermal operation with low maintenance and low human activity, healthy ecosystem and abundance of prey species option. Geothermal power plant operation has potential to operate in-sync with biodiversity conservation. Javan leopard existence as keystone species around geothermal operation is a sign that the ecosystem is healthy and could provide their needs to survive. It is expected that the existence of geothermal operations can positively influence efforts to maintain forest functions and biodiversity due to geothermal operation dependence to ecosystem services which is water and geothermal.

ACKNOWLEDGEMENTS

We would like to thank Star Energy Geothermal Darajat II, Limited for supporting this research by providing necessary equipment for the research and financial support for the research and publication. We would also like to thank Garut BKSDA wilayah V for supporting this research by sharing valuable information of the research field site, provided permit to enter and conducted the research within the Gunung Papandayan Nature Park, and supervised the activities. This research was conducted during the covid-19 pandemic. The success of this study is due to the compliance of the parties involved with the covid-19 protocol.

Keywords: Pertamina-mentored SMEs, Geothermal Coffee, Canaya, Liberica, Kampar, Commercial Coffeeshop Scheme, Marketing Innovation

ABSTRACT

This study aims to develop innovative marketing strategies for coffee products utilizing geothermal energy, produced by Pertamina-mentored SMEs under the Canaya, Liberica, and Kampar brands, through a commercial coffeeshop scheme for the public with the brand "KabarBaik RB Coffeeshop". Pertamina-mentored SMEs often face challenges in marketing and branding their coffee products in domestic or global.

The big concept and road map of the study will be about sustainability where all the product and residu will be re-used without harming the environment within the program of Rumah BUMN Riau as one of CSR program of PT Pertamina Geothermal Energy. Therefore, this study will be a pilot project to SME's of Pertamina to optimize the marketing and support the ESG and SDG implementation internally. On the other hand, this coffeeshop is operated by the person with disabilities as the effort to create more jobs for handicapped or disabilities communities.

The research expects to identify marketing innovations to increase sales of Pertamina-mentored SME coffee products. These innovations may include: Developing strong branding, creating unique and appealing logos, taglines, and brand identities, designing attractive packaging, Utilizing high-quality materials and creative designs, leveraging social media, promoting coffee products to a wider consumer base with the tagline as "Simplicity in Silence" means that , participating in coffee exhibitions and festivals, increasing brand awareness and reaching new customers, developing partnerships with coffeeshops, expanding the distribution network for coffee products. By implementing these marketing innovations, the study hopes to increase sales of Pertamina-mentored SME coffee products and enhance their competitiveness within the Indonesian coffee market.

1. INTRODUCTION

MSMEs (Micro, Small and Medium Enterprises) according to Ministry of State Owned Entreprise and Ministry of Cooperatives and Small and Medium Enterprises are types of businesses that have certain criteria, such as number of employees, turnover and limited capital.

Classification :

- Micro business: employees <10 people, capital/assets <50 million, turnover <300 million/year
- Small Businesses: employees 10-49 people, capital/assets 50 million – 500 million, turnover >300 million – 2.5M/year
- Medium Businesses : 50-200 employees, capital/assets 500 million – 10 billion, >2.5M – 50 M/year

Beneficiaries: Individuals, groups or business entities who directly or indirectly receive benefits from programs, services or initiatives from Rumah BUMN, while the beneficiaries are MSMEs, cooperatives, or individuals who want to start business.

- Direct: Individuals, groups or entities that directly benefit from programs, services and initiatives of Rumah BUMN, for example training participants, guidance, or assistance with access to markets.
- Indirect: Individuals, groups or entities that are not directly involved in participating in the Rumah BUMN program but receive impacts or benefits from program implementation as a domino effect or changes that occur in the surrounding environment.

Types of benefits to SME's community or individuals including Technical, Training, Business Assistance, Market Access, Financing etc. to help improve prosperity, growth and competitiveness in the business world.

2. RUMAH BUMN

Rumah BUMN is a forum for CSR accountability Pertamina (Persero) and its subsidiaries against Ministry of State Owned Entreprise of Indonesia. Rumah BUMN can be a forum for synergy and collaboration in the CSR program for all PT Pertamina (Persero) business units and its subsidiaries, especially in Riau region. Rumah BUMN views the need for synergy and collaboration in the CSR program, especially in terms of developing Pertamina-assisted MSMEs so that there is no overlapping of programs. CSR and funding for MSMEs assisted by Pertamina in Riau Region.

Rumah BUMN has sufficient capacity to support assisted MSMEs in Riau is including registration, guidance, development, and certification which can make the MSMEs that are fostered rise to a higher class and be able to compete on the global stage. Rumah BUMN needs support from all Pertamina business units in the Riau region to improve portfolio in order to achieve operational independence and increase innovation for assisted MSMEs.

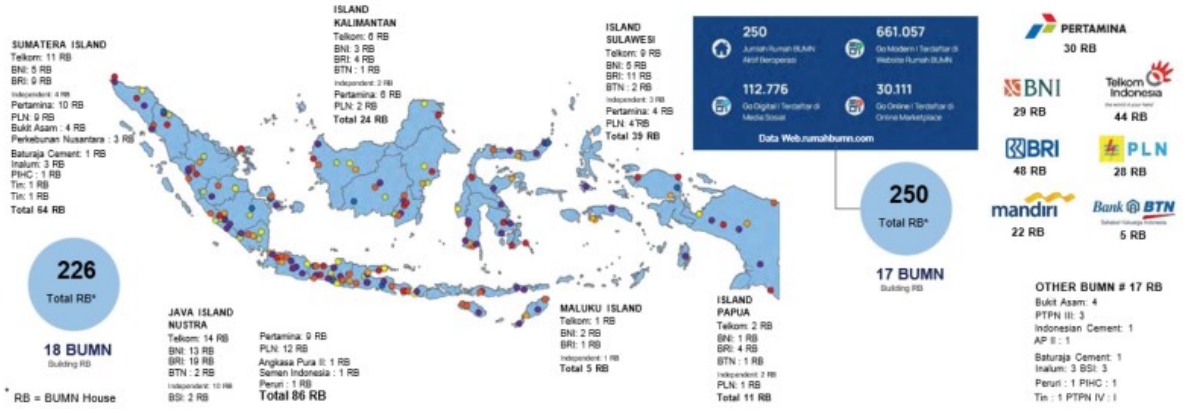

Figure 1: The Distribution Map of Rumah BUMN in Indonesia.

Rumah BUMN distribution map in Figure 1, a program by Pertamina to support micro, small, and medium enterprises (MSMEs), has a wide distribution across Indonesia. While I can't provide the exact number of locations due to privacy concerns, here's what I can tell you:

- Extensive Network: There are over 500 Rumah BUMN locations spread throughout Indonesia.
- Nationwide Presence: Rumah BUMN aims to be present in every major city and province.
- Targeted Locations: They prioritize establishing locations in areas with a high concentration of MSMEs.

PT Pertamina Geothermal Energy as one of the subsidiary of PT Pertamina (Persero) had already assigned by Ministry of State Owned Entreprise of Indonesia to develop and empower SME's as the proof of its existence to the SME communities all around Indonesia. Pertamina's Rumah BUMN program empowers micro, small, and medium enterprises (MSMEs) across Indonesia. The program boasts a presence in various regions, including Aceh Timur, Aceh Tamiang, Kepulauan Meranti, Dumai, Pekanbaru, Bengkulu, Rejang Lebong, Serdang Bedagai, Ogan Ilir, Kerinci, Lampung Tengah, Kepulauan Seribu, Purbalingga, Temanggung, Mojokerto, Situbondo, Klungkung, Sumbawa Barat, Dompu, Lombok Timur, Banjarmasin, Balikpapan, Berau, Palangkaraya, Seruyan, Sanggau, Bone Bolango, Parigi Moutong, Minahasa Selatan, and Tojo Una-una (Shown in Figure 1).

Standardization of Rumah BUMN MSMEs capabilities:

- Product Standards: technical specifications, production methods, raw materials, and manufacturing processes according to quality standards, security, applicable regulations.
- Process Standards: procedures and business practices for MSMEs in carrying out operations including quality management, risk, environment, etc.
- Service Standards: service quality related to response time, reliability, customer satisfaction, and internal ethical standards service
- Management Standards: standards of general management practices such as strategic planning, HR, finance, marketing, and operations for the sustainability of MSME businesses.

2.1 Rumah BUMN Riau

Rumah BUMN Riau has a mission in empowering MSMEs in Pekanbaru Rumah BUMN Riau is a non-profit organization, plays a vital role in supporting the growth of micro, small, and medium enterprises (MSMEs) in Pekanbaru. Their program operates like a well-oiled machine, fostering MSME development through a series of interconnected initiatives.

2.1.1 The Role of Rumah BUMN Riau

Rumah BUMN creates a comprehensive program that empowers MSMEs to flourish while fostering a spirit of social responsibility within the business community of Pekanbaru. These are several roles of Rumah BUMN Riau as follows :

- **Cultivating the Next Generation of Entrepreneurs**
  The program begins with a focus on millennials. Rumah BUMN establishes a "Millennials Activity Center" – a dedicated space for young people to learn and grow as future business leaders. This center offers resources for studying business, internship opportunities, and participation in specially designed millennial programs organized by BUMNs (State-Owned Enterprises).

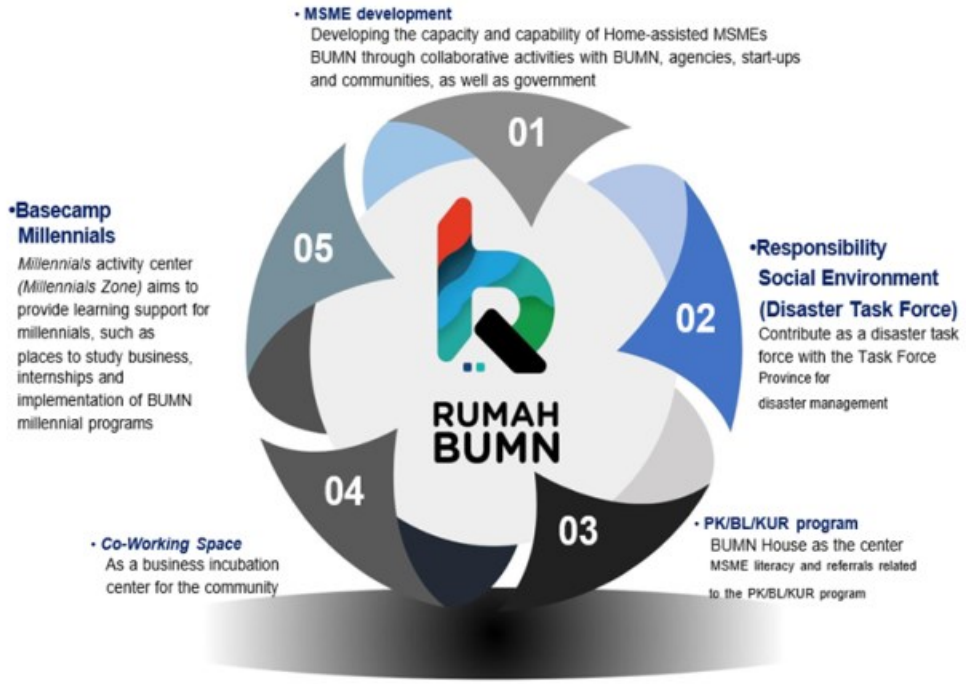

Figure 2: The Role of Rumah BUMN Riau in Indonesia.

- **Building Capacity and Capability**
  At the core of the program lies MSME development. Rumah BUMN works collaboratively with BUMNs, government agencies, startups, communities, and the government itself to empower MSMEs. Through these collaborations, they provide resources and training programs that enhance the capacity and capability of local businesses.
- **Nurturing Businesses within a Supportive Environments**
  The program offers a dedicated "Co-Working Space" that functions as a business incubator. This space fosters MSME literacy by providing resources and guidance. Additionally, the Co-Working Space acts as a referral center, connecting entrepreneurs with relevant government credit programs like PK/BL/KUR, which can provide crucial financial support for business growth.
- **Extending a Helping Hand**
  The program goes beyond just business development. Rumah BUMN recognizes the importance of social responsibility. The final stage emphasizes "Responsibility (Social Environment)" and participation in a "Disaster Task Force." This initiative encourages MSMEs to contribute to the community by working alongside the Provincial Task Force during disaster relief efforts.

2.1.2 The Ecosystem of Rumah BUMN Riau

Rumah BUMN Riau acts as a vital hub for empowering micro, small, and medium enterprises (MSMEs) across the Riau province in Indonesia. It fosters a comprehensive ecosystem that equips MSMEs with the tools and resources they need to thrive.

- **A Multi-Layered Approach to Supporting MSMEs**

Figure 4 depicts a diagram outlining the key components of Rumah BUMN's program to support micro, small, and medium enterprises (MSMEs) in Indonesia. The diagram uses a circular structure with arrows indicating the interconnectedness of the various program elements.

- **Central Hub: Rumah BUMN Riau**
  At the center of the circle sits the text "RUMAH BUMN" with the organization's logo. This central placement emphasizes Rumah BUMN as the core entity facilitating MSME development.
- **Empowering the Next Generation**
  Rumah BUMN Riau become the center provides millennials with resources for business education, internship opportunities, and participation in specific programs designed by BUMNs (State-Owned Enterprises) to cultivate young entrepreneurial talent.
- **Strengthening MSME Capacity**
  Rumah BUMN's collaborative efforts to enhance MSME capabilities. They achieve this by working with various stakeholders, including BUMNs, government agencies, startups, local communities, and the government itself. Through these partnerships, Rumah BUMN creates and delivers programs that strengthen the capacity and capabilities of MSMEs in the region. On the other hand, Rumah BUMN Riau provide all the SME's products to be displayed in the outlet gallery as shown in Figure 3 to support the sales and marketing of their products.

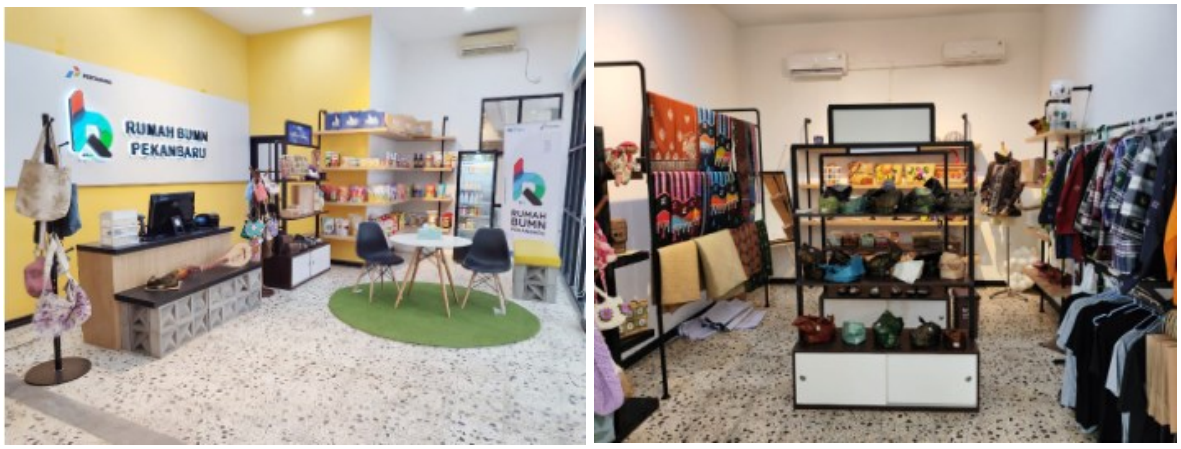

Figure 3: Outlet Gallery of Rumah BUMN Pekanbaru to Display SME's Products.

Figure 4: The Ecosystem of Rumah BUMN in Indonesia.

- **Providing a Supportive Ecosystem**
  Rumah BUMN Riau as The Co-Working Space functions as a business incubator, offering resources and guidance specifically geared towards MSME literacy. It further emphasizes the role of the Co-Working Space as a referral center, connecting entrepreneurs with relevant government credit programs (PK/BL/KUR) that provide financial aid crucial for business growth.
- **Fostering Social Responsibility**
  Represented by an icon of people helping people, delves into Rumah BUMN's initiative beyond pure business development. The text describes "Responsibility (Social Environment)" with a focus on participation in a "Disaster Task Force." This program element highlights Rumah BUMN's commitment to social responsibility. It encourages MSMEs to give back to the community by working alongside the Provincial Task Force during disaster relief efforts.

3. RESULT

KabarBaik RB coffeeshop is one of the business innovation from Rumah BUMN Riau which is located in Pekanbaru to optimize the sales and marketing of geothermal coffee product from PT Pertamina Geothermal Energy CSR program, where some of them produced using the direct heat of geothermal fluids from the geothermal production. The following are social business model canvas of KabarBaik RB Coffeeshop.

A. Social Project Objective:

To empower Pertamina Geothermal Energy SMEs through "KabarBaik RB Coffee" in Figure 5, creating jobs for people with disabilities, promoting sustainable practices, and building a collaborative ecosystem with various stakeholders to drive social and economic impact.

Figure 5. The Appearance and Existence of KabarBaik RB Coffeeshop in Pekanbaru (Canaya Coffee from Kamojang, Latif Coffee from Lumut Balai, and Brown Sugar from Lahendong).

B. Problem:

In addition to previous challenges, address the need for innovative marketing strategies and collaborative partnerships to ensure the coffee shop's sustainability and maximize its social impact. The other problem and challenges are the existing of established and fancy coffeeshop surroung this coffeeshop which can be a big deal for visitor to consider to come and buy at this coffee-shop with its simplicity and their socio-preneur scheme.

C. Proposed Solution:

- Implement a multi-faceted marketing strategy focusing on ESG and sustainability:
  This strategy will integrate environmental, social, and governance aspects into all marketing efforts. It will highlight the coffee shop's use of locally-sourced, sustainable coffee beans, waste reduction initiatives, and eco-friendly practices. Social impact will be showcased through stories of deaf employees and local SME partners. The governance aspect will be addressed through transparent communication of decision-making processes and regular impact reports. Sustainability will be promoted through educational content, workshops, and a themed menu, all designed to engage customers in the shop's mission and encourage responsible consumption.

- Develop partnerships with state-owned enterprises, government agencies, private sector, and youth communities:
  KabarBaik RB Coffee will forge strategic partnerships across various sectors to expand its reach and impact. For state-owned enterprises and private sector companies, it will offer corporate packages, employee discounts, and collaborative CSR initiatives. Government partnerships will involve participation in social and environmental programs, hosting policy discussions, and supporting local SME initiatives. Youth community engagement will focus on providing internship opportunities, hosting entrepreneurship workshops, and collaborating on social media campaigns. These partnerships will not only drive business growth but also create a supportive ecosystem for the coffee shop's social and environmental mission..

- Create a social media presence that highlights social impact and sustainability efforts:
  The coffee shop will develop a robust social media strategy across platforms like Instagram, TikTok, Facebook, and LinkedIn, each tailored to the platform's strengths. Content will focus on showcasing the shop's social impact and sustainability efforts through visually appealing posts, short-form videos, and longer-form content. Regular features will include a "Meet the Maker" series highlighting local SME products, "Sustainability Tip of the Week", and "Impact Spotlight" showcasing the shop's initiatives. Engagement will be fostered through user-generated content campaigns, interactive polls, and live Q&A sessions. Collaborations with local eco-influencers, social activists, and youth community leaders will help expand reach and credibility, creating a dynamic and impactful social media presence that aligns with the shop's values and mission.

D. Target Beneficiaries:

- Local youth communities:
  KabarBaik RB Coffee will actively engage and support local youth communities in Pekanbaru and the surrounding Riau region. This group includes students, young professionals, and budding entrepreneurs aged 18-35. The coffee shop will serve as a hub for youth-oriented activities, offering a space for networking, skill-building workshops, and collaborative projects. By providing internship opportunities, hosting youth-led events, and showcasing young local talent, the coffee shop aims to empower this demographic. The goal is to nurture a new generation of socially and environmentally conscious leaders who can drive sustainable development in the region, while also cultivating a loyal customer base that aligns with the shop's values and vision for the future.

- Environmentally and socially conscious consumers
  This target group comprises individuals who prioritize sustainability and social impact in their purchasing decisions. These consumers, ranging from young adults to seniors, are willing to pay a premium for products and experiences that align with their values. KabarBaik RB Coffee will cater to this group by offering ethically sourced coffee, eco-friendly packaging, and a menu that includes plant-based and locally sourced options. The shop's commitment to employing deaf individuals and supporting local SMEs will resonate with these consumers' desire for social impact. By providing a space that not only serves quality coffee but also educates about sustainability and facilitates community engagement, the coffee shop aims to become a preferred destination for this growing segment of mindful consumers, fostering loyalty and word-of-mouth promotion.

- Corporate and government partners looking for CSR opportunities
  KabarBaik RB Coffee will position itself as an attractive partner for corporations and government agencies seeking meaningful Corporate Social Responsibility (CSR) initiatives. This group includes local and national companies, state-owned enterprises, and government departments interested in demonstrating their commitment to social and environmental causes. The coffee shop will offer these partners unique opportunities to engage in impactful CSR activities, such as sponsoring skills training for deaf employees, supporting local SME product showcases, or collaborating on sustainability workshops. By aligning with KabarBaik RB Coffee's mission, these partners can enhance their public image, engage their employees in meaningful volunteer work, and contribute to local community development. The coffee shop will benefit from increased visibility, potential funding, and expanded networks, creating a win-win situation that amplifies its social and environmental impact.

E. Forms of Activities:

Marketing and Partnerships:

- Develop and maintain an engaging social media presence; KabarBaik RB Coffee will create and curate compelling content across various social media platforms, showcasing its products, sustainability initiatives, and social impact to build brand awareness and foster community engagement.

- Organize sustainability-themed events and workshops; The coffee shop will host regular events and workshops focused on sustainability topics, such as eco-friendly living, responsible consumption, and social entrepreneurship, to educate and inspire its customers and the wider community.
- Collaborate with youth communities for events and promotions; By partnering with local youth organizations and student groups, KabarBaik RB Coffee will co-create events, campaigns, and promotional activities that resonate with young audiences and promote the shop's mission.
- Establish partnership programs with state-owned enterprises, government agencies, and private companies; The coffee shop will develop tailored partnership programs offering corporate packages, collaborative CSR initiatives, and co-branded products to engage larger organizations and expand its reach and impact.
- Create loyalty programs for corporate partners and regular customers; KabarBaik RB Coffee will implement a multi-tiered loyalty program that rewards both individual customers and corporate partners for their purchases, participation in sustainability initiatives, and engagement with the shop's social mission.

F. Stakeholders/Partners:

- State-owned enterprises in Pekanbaru and surrounding areas:
  KabarBaik RB Coffee will engage with state-owned enterprises to create mutually beneficial partnerships, offering corporate packages, employee engagement programs, and collaborative CSR initiatives that align with both parties' social and environmental goals.
- Local and regional government agencies:
  The coffee shop will collaborate with government agencies to support local economic development, participate in public-private partnerships, and contribute to policy discussions on sustainability and social inclusion.Youth communities and organizations in Pekanbaru
- Private sector companies interested in CSR:
  KabarBaik RB Coffee will partner with socially responsible businesses to develop joint initiatives, such as employee volunteer programs, co-branded sustainable products, and sponsored events that amplify both parties' positive impact on the community.
- Youth communities and organizations in Pekanbaru:
  By fostering relationships with local youth groups, the coffee shop will create opportunities for young people to engage in sustainability projects, gain work experience, and contribute to community development initiatives.
- Social media influencers and content creators
  KabarBaik RB Coffee will collaborate with local influencers and content creators who align with its values to produce authentic, engaging content that promotes the shop's mission, products, and impact to a wider audience.

G. Project Duration:

Remains 8 months for the initial phase, with long-term operation plans

H. Challenges:

- Building and maintaining effective partnerships with diverse stakeholders; Forge strong, collaborative relationships with a variety of groups to achieve shared objectives.
- Consistently creating engaging content for social media; Regularly develop content that captures attention and sparks interaction on social media platforms.
- Balancing commercial success with social and environmental goals; Strive for profitability while also considering positive social impact and environmental responsibility.

I. Required Budget:

Increase to Rp. 150,000,000 to account for additional marketing and partnership development efforts

J. Project Social Outcomes:

- Increased awareness of sustainable and inclusive business practices; Educating and motivating people to adopt business models that benefit both society and the environment. This can involve showcasing success stories, highlighting the positive social and environmental impact of sustainable practices, and offering resources for businesses to implement them.

- Stronger collaborative ecosystem among businesses, government, and communities: Fostering a network where all parties work together to achieve shared goals for economic and social development. This can involve encouraging open communication and collaboration between businesses, government agencies, and community organizations, allowing for joint initiatives that address local needs and create a more supportive environment for business growth.
- Enhanced visibility and support for local SMEs and their products; Elevating the profile and providing resources to empower small and medium-sized enterprises in a specific location. This might involve creating platforms for SMEs to showcase their products and services, offering training and mentorship programs to help them develop their business skills, and advocating for policies that support the growth of local businesses.

K. Impact of Activities:

- Community Engagement: Fostering a sense of community and shared purpose among diverse stakeholders. This impact strengthens social bonds and collaboration by creating opportunities for people from various backgrounds to connect, build trust, and work together towards common goals that benefit the entire community.
- Sustainable Consumption: Promoting environmentally and socially responsible consumer behavior. This impact encourages people to make conscious choices when purchasing goods and services, prioritizing products that minimize environmental damage and support ethical labor practices. This can lead to a more sustainable and responsible consumer culture.
- Youth Empowerment: Engaging and inspiring local youth through collaborative initiatives. This impact provides young people with opportunities to participate in decision-making processes, develop their skills, and contribute to their communities. It fosters a sense of agency and empowers them to become active and responsible citizens who shape the future.

L. Post-Project Sustainability Plan:

- Develop a robust partner management system to maintain and grow collaborations; This system would streamline communication, track progress on joint initiatives, and ensure clear roles and responsibilities for each partner. This fosters long-term, mutually beneficial partnerships that contribute to achieving shared goals.
- Create a content calendar and strategy for ongoing social media engagement; A well-defined content calendar helps plan and publish engaging content regularly, keeping audiences informed and interested. The strategy component ensures the content aligns with overall goals, resonates with target audiences, and drives desired actions on social media platforms.
- Establish an advisory board including representatives from key stakeholder groups; An advisory board offers valuable insights, expertise, and connections from diverse perspectives. Including representatives from key stakeholder groups like businesses, government, and community organizations fosters a more inclusive approach and ensures initiatives address the needs of all involved.
- Implement a data-driven approach to measure and communicate social and environmental impact; By collecting and analyzing data, this approach allows for a more accurate assessment of the program's effectiveness. It enables the program to demonstrate the positive change it creates in terms of social and environmental outcomes, fostering transparency and accountability.

Marketing Strategy Highlights:

- Social Media Engagement: Develop a strong presence on platforms like Instagram, TikTok, and Facebook, showcasing the coffee shop's social impact, sustainability efforts, and unique offerings.
    - Platforms: Develop a strong presence on Instagram, TikTok, and Facebook, reaching a wider audience through the most popular social media channels.
    - Content Strategy: Showcase the coffee shop's social impact through engaging content (e.g., employee stories, community events), highlight sustainability efforts (e.g., sourcing, waste reduction), and promote unique offerings (e.g., signature drinks, limited-edition merchandise).
    - Goal: Build brand loyalty, attract customers who value social responsibility, and generate excitement about the coffee shop's offerings.
- ESG and Sustainability Theming: Center all marketing materials and in-store experiences around environmental, social, and governance (ESG) principles and sustainability practices.
    - Marketing Materials: Center all marketing materials around environmental, social, and governance (ESG) principles. This can include using recycled or sustainable packaging, incorporating eco-friendly themes in visuals, and highlighting ethical sourcing practices.

- In-Store Experience: Extend the ESG focus to the in-store experience. Offer reusable cups for discounts, display information about sustainability initiatives, and create a welcoming atmosphere that reflects the coffee shop's values.
- Goal: Attract environmentally and socially conscious customers, differentiate from competitors, and reinforce the brand's commitment to positive change.

Collaborative Partnerships:

- BUMN (State-Owned Enterprises): Develop corporate packages, host events, and create special promotions for employees.
- Government: Engage in public-private partnerships for social programs, host policy discussions, and participate in government-led initiatives.
- Private Sector: Offer corporate social responsibility (CSR) opportunities, create co-branded products, and develop employee engagement programs.
- Youth Communities: Organize youth-focused events, provide internship opportunities, and collaborate on social media campaigns.

Community Events: Host regular workshops, talks, and networking events centered around sustainability, entrepreneurship, and social impact.

Loyalty Program: Implement a points-based system that rewards not only purchases but also participation in sustainability initiatives and community events.

Impact Reporting: Regularly publish and promote impact reports highlighting the coffee shop's contribution to local SMEs, job creation for people with disabilities, and environmental sustainability.

Influencer Collaborations: Partner with local influencers and content creators who align with the brand's values to expand reach and credibility.

This enhanced strategy aims to create a vibrant ecosystem around "KabarBaik RB Coffee", positioning it not just as a coffee shop, but as a hub for sustainable business practices, community engagement, and social impact in Pekanbaru and the broader Riau region.

4. CONCLUSION

- KabarBaik RB Coffeeshop is a shining example of how a business can use geothermal product coffee as a force for good. By empowering local businesses, creating jobs for people with disabilities, promoting sustainable practices, and fostering a collaborative community, they're brewing a brighter future for Pekanbaru.
- Their innovative marketing strategies engage socially conscious customers, while their commitment to community engagement fosters a sense of shared purpose. By measuring their impact and continuously adapting their approach, KabarBaik RB Coffeeshop ensures long-term sustainability and maximizes their positive influence.
- KabarBaik RB Coffeeshop serves as a model for social entrepreneurship, inspiring others to use business as a tool for positive change. Their success story demonstrates the power of collaboration, environmental responsibility, and community engagement. In the end, they're not just brewing delicious coffee – they're brewing a better future, one cup at a time.
- KabarBaik RB Coffeeshop isn't just about serving delicious coffee; it's a social enterprise brewing a brighter future for Pekanbaru. They empower local businesses, create jobs for people with disabilities, promote sustainable practices, and foster a collaborative community through coffee. Their innovative marketing strategy is key to their success. Engaging social media content on platforms like Instagram, TikTok, and Facebook showcases their social impact stories, sustainability efforts, and unique offerings, attracting customers who value their mission. KabarBaik RB Coffeeshop integrates ESG principles into their marketing, using recycled materials, highlighting eco-friendly practices, and offering reusable cups, resonating with environmentally conscious consumers.

ACKNOWLEDGEMENT

KabarBaik RB Coffeeshop would like to express its sincere gratitude to Pertamina Geothermal Energy, a subsidiary of PT Pertamina Persero, for their invaluable support in supplying our coffee shop with high-quality coffee beans and brown sugar sourced directly from their geothermal fields. We would also like to extend our appreciation to the Ministry of State Owned Entreprise of Indonesia for establishing Rumah BUMN and providing the necessary funding through Rumah BUMN Riau, which serves as the mother institution for KabarBaik RB Coffeeshop.

Keywords: Geothermal Power Plant, Coal-Fired Power Plant, Comparison, Life Cycle Assessment, Environmental Impacts

ABSTRACT

Indonesia has 40% of the world's geothermal potential, equivalent to 28,617 MW. However, this potential has yet to be fully utilized, with only about 4.5% used for electricity generation. Despite the government's encouragement to build more geothermal power plants (GPPs) to support the energy mix and achieve net zero emissions targets, most of Indonesia's power generation still comes from coal-fired power plants (CFPPs), which make up 47.3% of the total generating capacity in the country, with a total capacity of 20.8 GW. Increasing the number of operating GPPs can help in reducing greenhouse gas emissions. On the other hand, adding more geothermal power generation units will have the opposite effect. However, there has not been comprehensive research comparing the environmental impacts of GPP with CFPP, which is the most common type of generator in Indonesia. In this study, we use the life cycle assessment (LCA) method to evaluate the environmental impact of existing GPP units, and then compare the results with existing CFPP units. This comparison aims to provide valuable insight into the environmental impacts of these two types of plants to help decision-makers and stakeholders make informed choices regarding the development and operation of GPPs and CFPPs in Indonesia, contributing to the development of a comprehensive net zero emissions strategy.

1. INTRODUCTION

Geothermal Power Plant (GPP) is an environmentally friendly power plant with a low environmental impact. Research comparing the environmental impact of GPP and CFPP-related environmental impacts, such as acidification and global warming potential (GWP), needs to be quantitatively assessed to ensure the advantages of CFPP in terms of environmental impact. Life Cycle Assessment (LCA) analyzes the environmental impact of a product, process, or system, such as a power plant, from fuel extraction to final disposal. Several methodologies, including ISO standards, TRACI, ReCiPe, CML, Ecoinvent, and ILCD, are used in this analysis process. Product Category Rules (PCR) (EPD International, 2021) were used to standardize the comparison of the LCA for specific products or product categories, enabling consistent comparisons of environmental impact categories. The product categories in this study were both types of CFPP and GPP.

Research on LCA of Geothermal Power Plants (GPP) in Indonesia is quite limited. Generally, the research still focuses on the environmental impacts of GPP operation. In a small-scale geothermal plant, Tampubolon (2023) found that the release of non-condensable gas (NCG) into the air from cooling towers contributes to acidification, which is the primary environmental impact at geothermal power plants. This finding was supported by a similar study at Wayang Windu GPP (Annisa & Rahardyan, 2018). Additionally, an LCA analysis at Kamojang GPP (Alfian Ardyansyah & Maya Sopha, 2018) revealed that the operational phase of GPP has the most significant environmental impact, particularly in terms of global warming potential (GWP) emissions and acidification. Another study at Patuha GPP also found that GWP and accidification impacts were more significant compared to other environmental impacts (Sondakh, 2022). To support Indonesia's net-zero emission strategy, it is essential to compare the environmental impacts of GPP using LCA with those of CFPP utilizing the same boundary system. Therefore, a research initiative was undertaken wherein LCA calculations using PCR were employed to analyze the environmental impact of a GPP unit in West Java and a CFPP unit in Banten. A quantitative comparison of the impacts in this category can offer new insights regarding quantitative environmental impacts.

2. MATERIAL AND METHODS

2.1 Power plant overview

This study used operational data from a 315 MW capacity CFPP in Banten and a 55 MW capacity GPP in West Java, Indonesia. Both power plants are base-load power plants connected to the Jawa-Madura-Bali (JAMALI)

grid. The chimney emissions from the CFPP, including CO_2, CO, SO_2, O_2, NOx, and PM2.5 from both units, were measured hourly by the continuous emission monitoring system (CEMS). The emissions data for the GPP were obtained from the Environmental Report. The environmental impacts of both types of PP were compared and assessed simultaneously using the LCA method. The data encompassed various inputs and outputs of both units' energy, materials, and emissions. The environmental impact of GPP was assessed and compared to that of CFPP.

Table 1: Operational Parameter of GPP and CFPP.

Parameter	Unit	GPP	CFPP
Operation days	days	365	276
Operation time	h	8760	6,624
Capacity factor	%	100	75.6
Fuel Consumption	t	-	1,063,232.2

2.2 LCA method

The LCA study referred to the guidelines for ISO14040:2006/Amd1:2020 and ISO 14044:2006/Amd2:2020. These guidelines outline four phases of LCA: goal and scope definition, inventory analysis, impact assessment, and interpretation. The study also considered the MOEF's LCA report preparation guidelines from 2021. It evaluated the environmental impact of GPP and CFPP operations, including fuel, chemicals, products, air, soil, and water emissions. To assess these impacts, the study used the openLCA data processing software with the Ecoinvent 3.8 database, which contains life cycle inventory data and emission factors. The study used the default impact categories and calculation methods specified in the Product Category Rules for Electricity, Steam, and Hot/Cold Water Generation and Distribution systems. It considered impact categories like GWP, Abiotic depletion (ADP) elements and Abiotic depletion (ADP) fossil, Acidification Potential (AP), Eutrophication (EP), Ozone layer depletion (ODP), Photochemical oxidation POFP, Water Use (WU). The study used various methodologies for assessing these categories, such as IPCC 100-year GWP for GWP assessment, CML-IA baseline (World 2000) methodology for EP, ADP elements and ADP fossil, AP and ReCiPe Midpoint (H) (2008) methodology for POFP. The AWARE approach was used for WU.

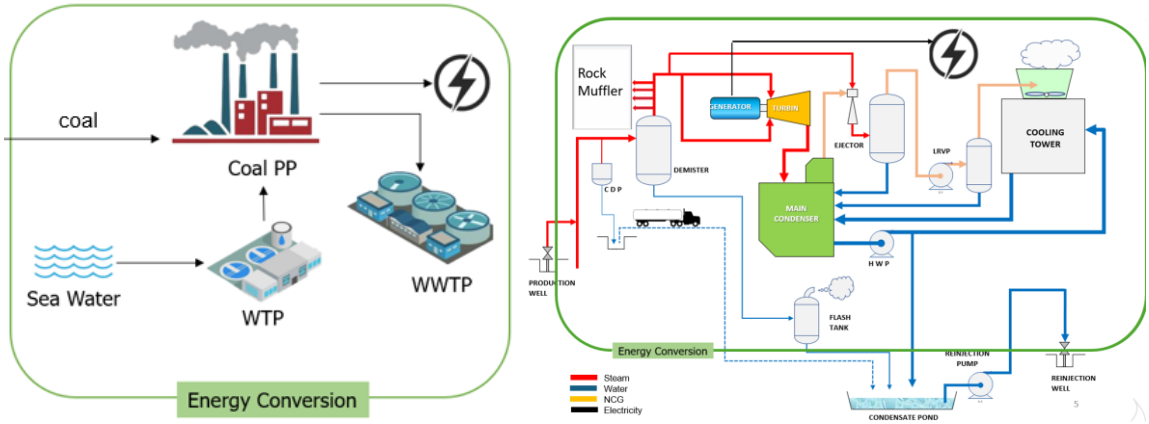

Figure 1: Boundary System (gate to gate) for CFPP and GPP.

2.1.1 Goal and scope definition

The first step in the Life Cycle Assessment (LCA) process is to define the objectives and scope. This stage determines the overall plan for conducting the LCA analysis. The objective is to calculate the amount of environmental impact during the operational process of procuring raw materials for coal and geothermal steam, as well as PP operation, based on the functional unit of 1 kWh of electricity produced. The functional unit is the main element that needs to be considered when comparing two different systems to normalize them, defining the environmental impact point of view related to the function of the identified system (Sala and Garcia, 2016). Both systems are from transportation fuel for the CFPP in Banten and piping transportation of geothermal steam for the GPP in West Java (gate to gate). The study acquired primary data from CFPP (Febijanto et al., 2024) and secondary data from GPP. The collected data for both power plants included geothermal steam, coal fuel, chemicals, water requirements, internal electricity usage, emissions, and waste. The background data was obtained from the literature and the Ecoinvent 3.8 dataset. Figure 1 illustrates the boundaries of the GPP and CFPP from gate to gate.

The coal supply chain starts with the receipt of coal at the power plant (PP), followed by the combustion of coal and processing of water at the water treatment plant (WTP) and wastewater treatment plant (WWTP) stages. Meanwhile, geothermal power plants focus on the operation of power plants to generate electricity by utilizing steam derived from geothermal heat. Overall, this study offers a thorough and detailed analysis of the supply chains involved in the CFPP and GPP operations. The data obtained from both primary and background sources help to illuminate the different environmental impacts of both types of power plants and provide valuable insights for comparing them as part of the national renewable energy development strategy and for future research and development in this field.

2.2.2 Life cycle inventory

The second step of LCA is known as life cycle inventory (LCI) analysis. It is a technique used to measure the amount of energy used, raw materials used, and environmental effects at every stage of a system's evaluation (EPD International, 2021). According to ISO14040:2006/Amd1:2020, the LCI considers the product's input and output at every stage of its life cycle. This section explains the system boundary for each scenario, as well as the data sources and underlying presumptions. During the inventory stage of the LCA process, the energy flow from fuel consumption, mass balance at each stage, and operational processes, including steam flow from wellheads and the combustion of coal to produce electricity, WTP, and WWTP, were all analyzed.

2.2.3 Impact analysis

When evaluating the environmental impact of inventory data, it is called life cycle impact analysis (LCIA). During this process, the identified environmental flows (inventory analysis) and the defined impact categories (goal and scope definitions) are used to assess potential impacts. The evaluation of each scenario's possible environmental effects utilized the specifications outlined in the PCR for Electricity Generation) (EPD International, 2021). Impact categories considered in this study included GWP, AP, EP, ODP, POFP, ADP elements, ADP fossil, WS, and LU.

2.3 Construction of the scenario

The comparison of environmental impacts in the GPP and CFPP operational phases was carried out based on the GPP scenario operating for 8760 hours in 2023, while the CFPP was based on actual operations in 2022.

3. RESULT AND DISCUSSION

The results of calculating environmental impact categories for CFPP and GPP are shown Table 2.

Table 2: LCIA results for GPP compared to CFPP.

Impact categories	Methodology	Unit	CFPP	GPP
ADP, elements	cml baseline	kg Sb eq	3.40×10^{-10}	0
ADP, fossil fuels	cml baseline	MJ	2.13×10^{-4}	0
EP	cml baseline	kg PO4--- eq	2.66×10^{-4}	0.12×10^{-4}
ODP (optional)	cml baseline	kg CFC-11 eq	3.25×10^{-12}	0
POFP	ei Recipe midpoint H vs 1.3	kg NMVOC	2.17×10^{-3}	0.018×10^{-3}
WU	AWARE	m^3 eq	5.18×10^{-3}	0.07×10^{-3}
GWP $_{100a}$	IPCC 2021 GWP 100	kg CO_2 eq	1.19	8.42×10^{-3}
AP (fate not incl.)	CML non baseline	kg SO_2 eq	1.41×10^{-3}	3.92×10^{-3}

Table 3: LCIA results for GPP compared to CFPP in the different methodology (kWh).

Impact categories	Methodology	Unit	CFPP	GPP
AP	Tracy 2.1	kg SO_2 eq	3.44×10^{-3}	3.92×10^{-3}
AP	Recipe midpoint H	kg SO_2 eq	2.76×10^{-3}	0.01×10^{-3}
AP	Cml baseline	kg SO_2 eq	1.00×10^{-3}	0.052×10^{-3}
AP (fate not incl.)	Cml non baseline	kg SO_2 eq	1.41×10^{-3}	3.92×10^{-3}

The overall environmental impact per electricity production from GPP is lower than CFPP, except for AP. Regarding the AP results, this result strongly supports the results of previous research (Alfian Ardyansyah & Maya Sopha, 2018; Annisa & Rahardyan, 2018; Pangihutan Christian Tampubolon et al., 2022; Sondakh, 2022), that the biggest environmental impact of GPP was AP. The AP mainly was caused by non-condensable gas released into the air from the cooling tower.

The selection method in LCA is the important point, Table 3 indicates AP result from several methodologies in LCA analysis. Each LCA methodology is a combination of several different factors and processes, which will influence the results. The CML Non-Baseline (Guinee J.B, 2002) and Tracy 2.1 (Bare et al., 2003) methodologies consider hydrogen sulfide (H_2S) as an AP contributor, while the ReCiPe Midpoint H (Goedkoop et al., 2009) and CML Baseline (Guinee J.B, 2002) methodologies do not consider H_2S as an AP contributor. The inclusion of H_2S will provide the result with higher AP potential, especially for power plants with high H_2S emissions such as in GPP. From the data obtained, the results of the AP impact were not caused by H_2S (98.38%) alone but by NH_3 (1.31%) and NOx (0.30%). For comparison, the AP impact on CFPP originated from Nitrogen Oxide, NOx which emitted from the combustion process in boiler furnace (Sigal et al., 2022). As shown in Table 2, the GWP impact in CFPP was 1.19 kgCO2eq/kWh, and in GPP was 0.00842 kgCO2eq/kWh. In this study, the H_2S emissions intensity in GPP was 2.05 gr/kWh. According to the previous study, the intensity in the others GPP was as follows, Wayang Windu GPP produced 2.54 gr/kWh, Kamojang GPP 0.14 gr/kWh, and Ulubelu GPP 1.68 gr/kWh (Edhi Budhi Soesilo & Heviati, 2015).

Naturally occurring gases (NCGs) found in geofluids are typically released into the atmosphere, except for hydrogen sulfide. Before releasing hydrogen sulfide, it must be scrubbed. However, due to growing concerns about greenhouse gas (CO_2) emissions, NCGs are now being compressed and reinjected into the reservoir along with the used geofluid. NCGs in geofluids can contribute to environmental AP, particularly if they contain gases such as carbon dioxide (CO_2) and hydrogen sulfide (H_2S) (Finster et al., 2015). When CO_2 dissolves in water, it can create carbonic acid (H_2CO_3), which lowers the pH of the water and causes AP. Meanwhile, H_2S can be oxidized to sulfuric acid (H_2SO_4), which can also lead to AP.

To mitigate the AP produced by GPP, several steps can be taken (Bošnjaković et al., 2019): 1) Use of Scrubber Technology: Scrubbers can reduce emissions of acid gases such as SO_2 by absorbing harmful gases and converting them into less dangerous substances before releasing them into the atmosphere. 2) Geothermal Fluid Reinjection: Returning used geothermal fluid into the reservoir can help reduce acid gas emissions into the atmosphere, maintain reservoir pressure, and reduce the risk of subsidence. 3) Emission Monitoring and Control: Installing a sophisticated real-time emissions monitoring system can measure and control acid gas emissions, allowing operators to take immediate corrective action if emissions exceed permitted limits. 4) Use of Neutralizing Chemicals: Adding neutralizing chemicals to geothermal fluids before release can help reduce acidity levels and prevent environmental AP.

4. CONCLUSION

The study results indicated that the influence of AP from GPP operations was more notable than the impact of AP from CFPP operations. Even though nearly all environmental impacts from GPP operations were lower, when comparing environmental impacts using the same methodology and boundary system, it becomes evident that we should focus more on the impact of AP from GPP.

PROPER Implementation in Star Energy Geothermal Darajat II, Limited

Muhammad Riyadhi and Micia Zaputi Rohimah

PT Star Energy

m.riyadhi@starenergy.co.id

Keywords: Cost efficiency, environmental performance, geothermal energy, innovation, PROPER

ABSTRACT

Operational processes are the backbone of every company. They are carefully planned out and carried out to maximize production and meet the company's objectives. However, these operational activities can exert significant impacts on the environment, yielding both beneficial and detrimental effects. From resource extraction and production processes to waste generation and emissions, every stage of industrial production entails environmental implications. Therefore, effective environmental management is crucial to preserve natural functions and minimize potential environmental impacts. In response to these challenges, the Indonesian Government has implemented various initiatives, including Program Penilaian Peringkat Kinerja Perusahaan dalam Pengelolaan Lingkungan (PROPER) as a public disclosure program for environmental compliance. This program was initiated to enhance active participation and company performance in environmental monitoring and management. Under PROPER, companies are categorized into five-color tiers—gold, green, blue, red, and black—based on their environmental performance. The program evaluates companies' compliance with environmental regulations, as well as its further initiatives to improve their overall environmental performance. The adoption of PROPER is also expected to promote diverse innovations within the production process. A company's dedication to environmental stewardship may stimulate the establishment of novel innovations for reducing environmental impacts. Through optimal resource utilization, companies can minimize raw material consumption and mitigate waste generation, thus realizing operational cost efficiency. This integrated approach not only improves environmental sustainability but also highlights the economic benefits of responsible environmental management. One of the companies actively engaging in the implementation of PROPER is Star Energy Geothermal Darajat II, Limited (SEGD). Specializing in geothermal power plant operations, SEGD has an installed power generation capacity of 274,5 MW, which is then distributed to the Java-Madura-Bali (JAMALI) interconnection system. Through its active participation in PROPER, SEGD consistently aims to improve its environmental performance. The company's effort in environmental management can be proven by the achievement of the gold PROPER award in 2022-2023, the highest tier award. This recognition emphasizes the company's dedication to conduct geothermal operations in harmony with environmental and social aspects, setting a commendable standard for the industry. This study aims to analyze the influence of PROPER implementation on SEGD's environmental performance and operational cost efficiency. The research was carried out using a descriptive method with a quantitative approach. This study shows that the implementation of PROPER in SEGD positively influences the company's environmental performance, resulting in reductions of energy use, water consumption, water pollutant load, CO_2 emissions, non-hazardous waste, hazardous waste, and preservation of biodiversity, including trees and animals. This study further shows that the implementation of PROPER reduces the operational costs of SEGD.

1. INTRODUCTION

The presence of a company in an area can have both negative and positive impacts. Industry can boost the regional economy by creating jobs for various skill levels, thereby increasing the employment rate and income level of the local community over the long term (Samsul et al., 2018). However, industry presence in a region can also pose challenges alongside their role in driving economic growth. From resource extraction and production processes to waste generation and emissions, every stage of industrial processes has the potential to generate environmental impacts, including on water, soil, and air. This impact is generally caused by waste produced, and its form can be liquid, gas, or particulate. Improper waste management can degrade environmental quality and have widespread impacts on humans, animals, and plants. For example, the discharge of industrial wastewater that is not adequately treated directly into water bodies can pollute the water and disrupt the aquatic ecosystem, making the water unsuitable for aquatic biota to live. Moreover, in the short term, exposure to polluted water can cause various human health problems, including skin irritation and diarrhea (Shultana & Khan, 2022). Some pollutants can accumulate in the human body over time, and in the long term, this will result in more severe health problems.

Therefore, effective environmental management is crucial to preserve natural functions and minimize potential environmental impacts. When a company implements environmental management strategies, it sets a series of practices and policies to prevent and reduce its environmental footprint. These strategies typically include

minimizing resource consumption, reducing waste generation, optimizing energy efficiency, and mitigating pollution emissions. Companies can significantly improve their environmental performance metrics by adhering to environmental regulations and adopting best practices (Nugrahani & Handono, 2023). Moreover, environmental management practices in companies are driven by standardization, regulations, and programs regarding environmental management. The Ministry of Environment and Forestry initiated a system to encourage corporate environmental management practices, namely the Company Performance Rating Assessment Program in Environmental Management (PROPER), as a public disclosure program for environmental compliance.

PROPER is an evaluation of company performance in environmental management by assessing compliance with applicable environmental regulations. PROPER's existence is hoped to increase business actors' awareness of complying with laws and regulations. Then, after this awareness is formed, the company is expected to improve its performance in managing and preserving the environment. Under PROPER, companies are categorized into five-color tiers based on their environmental performance: gold, green, blue, red, and black. The program evaluates companies' compliance with environmental regulations, as well as its further initiatives to improve their overall environmental performance (MoEF, 2021).

On the other hand, adopting PROPER also aims to promote diverse innovations within companies' production processes. A company's dedication to environmental stewardship may stimulate the development and implementation of novel innovations to reduce potential environmental impacts. These innovations often focus on optimizing resource utilization, which helps minimize raw material consumption and waste generation. This integrated approach improves environmental sustainability and highlights the economic benefits of responsible environmental management from upstream to downstream. For example, implementing new initiatives on waste management not only reduces the amount of waste generated by the company but also creates cost efficiencies related to the disposal of this waste (Wahyudianto & Boedisantoso, 2018).

One of the companies actively involved in the PROPER implementation is Star Energy Geothermal Darajat II, Limited (SEGD). SEGD operates a geothermal field that spans Garut Regency and Bandung Regency in West Java. The location of SEGD's wells falls within Natural Recretion Parks, Nature Reserves, Protection Forests, and residential areas. Specializing in geothermal power plant operations, SEGD has an installed power generation capacity of 274.5 MW, which is integrated into the Java-Madura-Bali (JAMALI) interconnection system. Through its active participation in PROPER, SEGD consistently aims to improve its environmental performance. The company's commitment to environmental management is highlighted by its achievement of the gold PROPER award in 2022-2023, the highest recognition in the program. This study aims to analyze the influence of PROPER implementation on SEGD's environmental performance and operational cost efficiency.

2. METHOD

The method used in this research is descriptive with a quantitative approach. In this method, variables are described as they are, supported by data in the form of numbers generated from the actual situation. The data obtained will be summarized and analyzed to provide a clear and detailed picture of the data that has been collected as it is (Sudirman et al., 2020). This research was conducted using secondary data in the form of PROPER implementation data at the Company in the 2022-2023 period obtained from reports or documents with the company's permission. Literature was also used to support this research, including regulations, publications, and papers related to the topic under study.

3. RESULT AND DISCUSSION

According to Putri (2018), the company's compliance assessment is based on fulfilling environmental documents, reporting requirements, and compliance with required environmental management. Apart from its activities having to fall under environmental management documents, the company must also report all environmental monitoring and management activities carried out to fulfill this criterion. Environmental management in question includes water pollution control, air pollution control, hazardous waste management, and non-hazardous waste management. After a company is temporarily declared to have fully complied with environmental regulations, the assessment will continue against criteria beyond compliance. The beyond compliance criteria look at the company's commitment to managing the environment beyond regulatory compliance. This includes integrating environmental management system practices, in a form of Life Cycle Assessment (LCA), energy efficiency, emission reduction, reduce, reuse, and recycle of hazardous waste and non hazardous waste, water and water pollution load reduction. Moreover, the company also has to integrate biodiversity protection, community development, and social innovation in the company's environmental management efforts (MoEF, 2021).

Beyond Compliance, in the context of PROPER, refers to companies not only meeting the minimum standards set by environmental regulations and laws but also proactively adopting practices that surpass these legal requirements. This demands a commitment to positively impacting the environment beyond mere regulatory

obligations. When a company seeks to exceed compliance standards, it can generate a broader and more positive environmental impact. During the 2022-2023 PROPER assessment period, SEGD implemented various eco-innovation programs across its operational activities as part of its commitment to improve their environmental performance. These initiatives included enhancing energy efficiency, reducing emissions, and implementing strategies for the reduction, reuse, and recycling of both hazardous and non-hazardous waste. Additionally, SEGD focused on reducing water consumption and water pollution loads as part of its comprehensive approach to environmental protection.

3.1 Energy Efficiency

Over time, production wells or steam supplies at geothermal power plant facilities often experience a decline in production. These issues arise due to various factors, such as blockages in drilling channels or accumulation of mineral deposits. To improve production, maintenance and repairs need to be carried out regularly, including cleaning the well and removing blockages. This ensures tha the quantity of steam flow will return to normal levels. Previously, was typically addressed by checking and repairing the well using acid and water. However, in 2022, SEGD initiated an innovative application aimed at enhancing steam production called "ANTI GUSUR BUMI."

Initially, geothermal wells experiencing decreased production are thoroughly evaluated. The condition of each production well is assessed and analyzed by the technical team. This assessment includes visual inspections, measurement of operational parameters, and analysis of production data before and after the production decline, aiming to pinpoint the root causes of the issues. If the main cause is identified as blockage or mineral deposits accumulation, cleaning the well becomes necessary. ANTI GUSUR BUMI addresses this by changing the wellhead pressure through repeated open-close cycles.

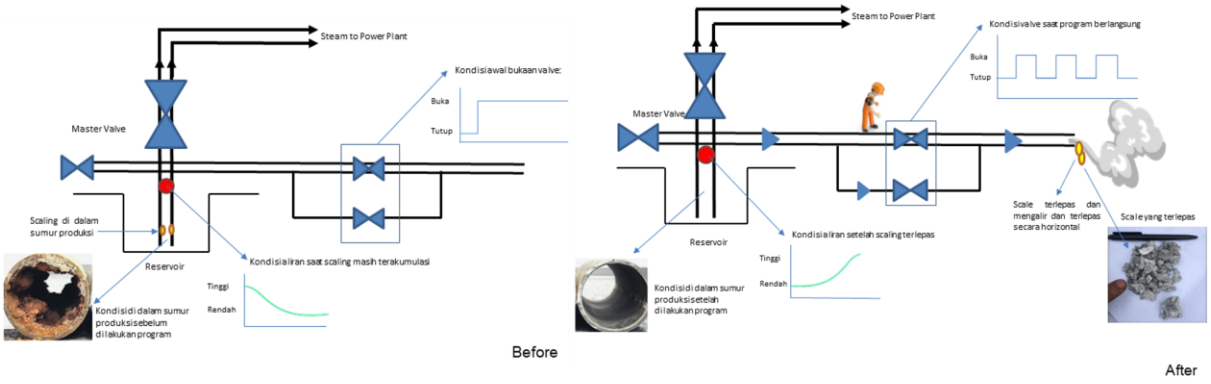

Figure 1: Scheme of ANTI GUSUR BUMI program.

This method was first implemented in Indonesia's geothermal energy sector by SEGD. From January 2022 to June 2023, this method was successfully applied to one of SEGD's production wells. This innovation successfully re-optimized the steam production rate of the DRJ-37 production well, increasing it from 14.5 kg/s to 19.9 kg/s and consequently, steam reserves from the well increased in absolute terms by 5.4 kg/s or equivalent to 3.2 MWe /well. Additionally, through the use of this innovation, SEGD achieved savings equivalent to the potential fuel use required for drilling one well, totaling 1,747 GJ per well. The implementation of this method enabled the company to achieve an energy efficiency of 34,266.71 GJ, equivalent to a cost efficiency of IDR 10,642,190,026.

3.2 Emission Reduction

In 2022, SEGD launched the SIAP TEMPUR innovation program aimed at resolving the issue of declining steam production in geothermal wells. This decline is primarily caused by scale buildup in the production well pipes, which reduces the steam supply needed to rotate turbines. Without proper cleaning and maintenance, this problem worsens, with steam production decreasing by 8% annually in geothermal facilities, potentially leading to daily generation losses of US$ 21,289.

Previously, high-pressure fluids were used with the Coiled Tubing Unit (CTU) to address this issue. However, this method involved lengthy preparation processes, including equipment mobilization and demobilization. Moreover, this method posed risks to the integrity of the well pipe casing. Apart from that, several significant health and safety hazards could potentially arise, such as exposure to toxic hydrogen sulfide gas, falling from heights, and exposure to condensate spills.

The SIAP TEMPUR program utilizes a descaling system employing an internally developed grinding tool pulled upwards through a wireline intervention technique, using mechanical force in a hammering action to remove scale. By implementing this program, SEGD optimizes steam production rates and increases steam reserves using simpler and more cost-effective equipment compared to traditional methods. SEGD leads this innovation in

Indonesia's geothermal energy sector, achieving an additional steam production of 21,518.04 MWh annually and reducing emissions by 18,720.69 tons of CO_2e, resulting in cost savings equivalent to IDR 23,653,216,826.

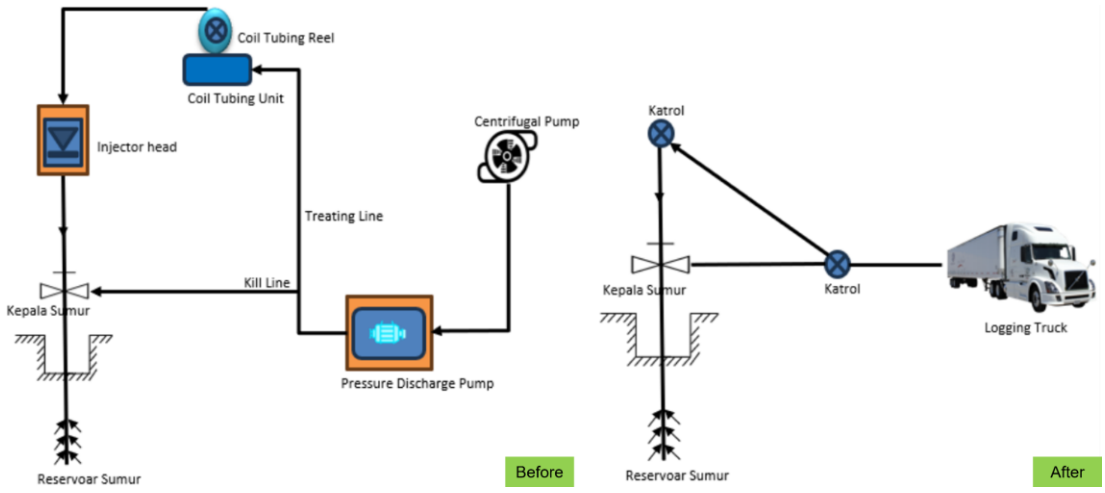

Figure 2: Scheme of SIAP TEMPUR program.

3.3 Reduce, Reuse, and Recycle of Hazardous Waste

To clean machine equipment, chemical cleaning products containing hazardous substances like grease and rust cleaners are often utilized. However, continuous use of these products contributes to an increase in hazardous waste and contaminated materials generation, including packaging, cleaning residues, and oil contaminated rag. Manual cleaning with these chemicals is suboptimal and time-consuming. Furthermore, their use increases the need for personal protective equipment for worker since the exposure to hazardous substances is higher.

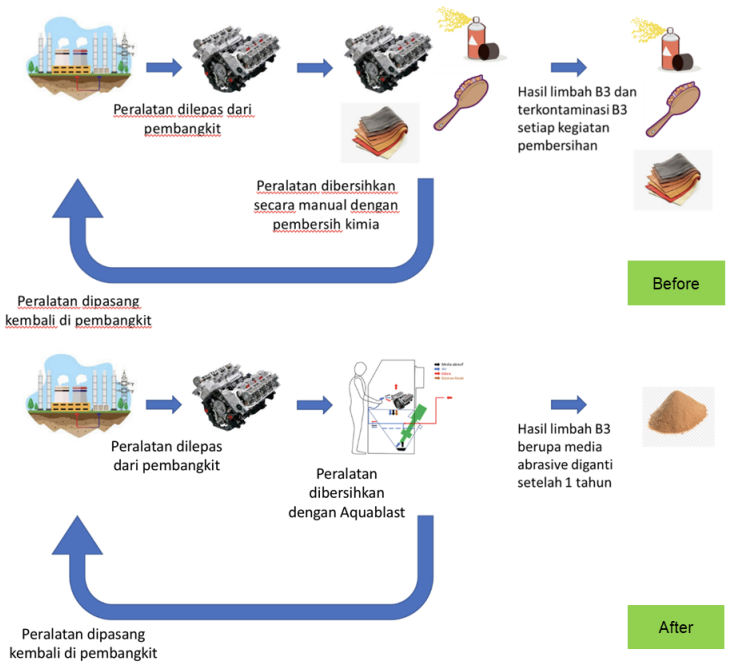

Figure 3: Scheme of PERAK LOGAM AMAN program.

In 2022, SEGD introduced an innovative approach called PERAK LOGAM AMAN for cleaning machine equipment and components using water-based solutions and abrasive materials. This pioneering method is the first of its kind in Indonesia's geothermal energy sector. The machine operates by combining compressed air with closed circulating water and abrasive materials. Using this system significantly reduces cleaning time by up to 14 hours per job. Moreover, it ensures effective equipment cleaning, enhancing reliability and preventing potential Lost Production Opportunity (LPO) losses totaling 20,800 per year. This method has proven effective in reducing hazardous waste generation by 0.575 tons, equivalent to cost savings to IDR 300,105,934.

3.4 Reduce, Reuse, and Recycle of Non-Hazardous Waste

In 2022, there was an upward trend in coffee consumption trends in Darajat, SEGD's operational area, leading to an increase in coffee residue generated by local cafes. Improper management of this waste can potentially clog waste channels and degrade wastewater quality. However, with appropriate processing, coffee residue waste can be turned into a valuable resource. Recognizing this opportunity, SEGD developed the PENIPU SUHU innovation program to repurpose non-hazardous waste, specifically coffee residue, for community benefit.

Figure 4: Scheme of PENIPU SUHU program.

Under the PENIPU SUHU program, coffee residue waste from SEGD's operational area is processed into a substrate supplement for maintaining Black Soldier Fly Larvae (BSFL). To enhance its nutrient content, the coffee residue undergoes fermentation to degrade phenolic compounds. Once its completely fermented, the coffee residue is added to containers where BSFL grow. This method has proven to accelerate BSF growth by only 10 days compared to conventional methods using fruit or vegetable waste. Through this initiative, the program successfully reduced non-hazardous waste generation by 0.81 tons, achieving a total cost efficiency of IDR 73,631,348.

3.5 Efficiency and Water Pollution Load Reduction

SEGD initiated the SIRSAK program to prevent drilling stuck by utilizing condensate water as a drilling fluid. Prior to this program, surface water from around the drilling site was used. However, drilling stuck often still occurs because the quality and availability of surface water were inconsistent and can not be guaranteed, leading to frequent drilling issues and increased costs. In response, SEGD introduced the innovative approach of utilizing condensate water flow as a drilling fluid. This switch ensures drilling operations remain uninterrupted because the fluid parameters can be closely monitored, maintaining quality consistently. Consequently, drilling schedules are adhered to and costs are controlled as planned. Through this program, SEGD has reduced water usage by 446,267.57 m^3, resulting in cost savings equivalent to IDR 10,932,216,697.

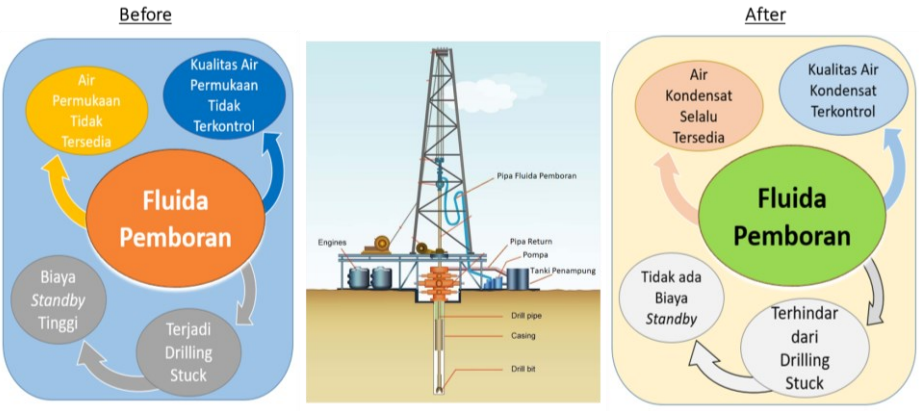

Figure 5: Scheme of SIRSAK program.

3.6 Biodiversity Protection

The Cikupakan area, situated within a river basin, faces erosion risks due to high river flows. The Darajat geothermal field is located in the Protected Forest area and the Mount Papandayan Nature Recreation Park. Within the Darajat Protected Forest, there is a noticable absence of hardwood trees, dominated instead by annual plants harvested every three months. This absence of hardwood trees in areas like Cigupakan, Well Pad S4, and Well Pad 18 results in insufficient canopy cover to mitigate the impact of rainwater on the soil. Additionally, the absence of varied plant species with soil-binding root systems and the lack of barriers contribute to soil erosion and increase the risk of landslides. Previous planting programs in the Darajat geothermal fields had low success rates because extensive annual plantations require sufficient sunlight, often disturbing and displacing newly planted vegetation.

In 2022, SEGD initiated the ASEP RESTO program, which builds upon previous efforts in planting on critical and conservation lands. Earlier plantings focused solely on endemic species found in the Darajat geothermal field area. However, the challenge with endemic plants lies in their slow growth rate, extending their vulnerable period and necessitating ongoing monitoring. To address this, the program integrates fast-growing plants like the Alder trees alongside endemic species. These endemic plants are planted alternately with fast-growing plants. Before the program, SEGD's planting efforts had a low success rate, with only about 25% of plants surviving. Hardwood plants, due to their slow growth, reached heights of 3-4 meters since planting in 2019, but recent plantings in 2021 saw minimal height increases of 5-10 cm due to low canopy cover around 10%.

Figure 5: Before and after the implementation of ASEP RESTO program.

Post-program implementation, the success rate rise up to 80%, achieving a 40% canopy cover. By using this method, the vegetation planted are more disease resistant and their growth is more sustainable. Notably, Alder trees saw a height increase, with seedlings growing from an average of 30 cm at planting to 2-3 meters within a year—a growth up to 1000%. This initiative also increase urban sustainability by contributing 0.6% of the required Green Open Space (RTH), filling a deficit of 613 hectares in Garut Regency. Furthermore, this program led to increase in the biodiversity index to 1.6118 H'Shannon-Wiener and the planting of 9,334 trees by 2023. This innovation has successfully contributed to improvements such as a potential reduction of 5,600 tons of CO_2 emissions and conservation of 162,692 m^3 of water.

3.6 Community Development

In Garut, flash floods often occur, and one of the factors causing this is the degradation of the upstream Cimanuk watershed area. The conversion of forest land that occurs reduces the soil's ability to absorb rainwater, thus causing erosion and flooding in the area. To overcome these challenges, SEGD introduced the Insan Smart initiative (Inovasi Sahabat Hutan Sinergi Menjaga Alam Darajat), which integrates environmental conservation with community economic interests. This initiative focuses on sustainable forest management involving local communities within SEGD's operational area. The goal is to improve the quality of the upstream forest in the Cimanuk watershed while enhancing community welfare.

Under Insan Smart, vulnerable groups, previously engaged in illegal land clearing for plantation within conservation area and wildlife hunting, have been transformed into conservation agents. They now actively participate in planting, maintaining, and patrolling forest areas. Additionally, to boost community income, these agents are involved in beekeeping activities for honey production in SEGD's forested areas. This economic incentive motivates the community to protect the Cimanuk watershed forest further more, showing a symbiotic relationship between sustainable forest management and community prosperity.

Figure 6: Community's active participation in Insan Smart program.

Previously, from 2016 to 2018, the community played a passive role in SEGD's conservation efforts, resulting in low tree survival rates. However, since the Insan Smart initiative launched in 2020, the community's role has evolved into proactive participation across all program stages, increasing tree survival rates to over 90%. This high survival rate not only indicates the success of community engagement but also correlates with increased carbon sequestration, erosion control, and water infiltration. The utilization of forest land for honey cultivation has provided alternative economic opportunities, reducing the need for illegal land clearing and hunting in the Darajat Forest area.

As of July 2023, the KTH Madu Darajat Berkah's average income is projected to reach IDR 22,100,000 for the year. Insan Smart strengthens community relationship with conservation targets, resulting in a greater responsibility and commitment awareness to environmental preservation and natural resource management. This innovation promotes social and economic development by offering sustainable livelihoods through environmentally-friendly economic activities, such as honey production and sustainable forest product harvesting. Moreover, the Madani Wangi program have an impact on the environment in the form of additional carbon reserves of 2,464.32 kg, potential water captured of 58.65 m^3, nutrient loss control of 150.18 kg, and CO_2 absorption of 7,290.3 tons/year.

By integrating environmental management programs and considerations into its core business strategy, SEGD effectively mitigates environmental risks. This approach not only increases operational efficiency and decreases costs but also strengthens relationships with local communities in its operational areas. Prioritizing environmental conservation and participating in initiatives like PROPER enables companies to contribute to sustainable development goals and ensure long-term environmental sustainability.

Table 1: Absolute value and cost efficiency from the implementation of eco-innovation programs.

Criteria	Absolute Value	Unit	Cost Efficiency
Energy Efficiency	34,266.71	GJ	Rp10,642,190.03
Emission Reduction	18,720.69	ton CO_2eq	Rp23,653,216.83
Reduse, Reuse, and Recycle of Hazardous Waste	0.58	ton	Rp300,105,934.00
Reduse, Reuse, and Recycle of Non-Hazardous Waste	0.81	ton	Rp73,631,348
Water and Water Pollution Load Reduction	446,267.57	m^3	Rp10,932,216,697
Biodiversity Protection	1.61	H'Shannon-Wiener	
	9,334.00	tree	
	31.00	species	
	2.97	Ha	
	5,600.00	ton CO_2	
	162,692.00	m^3	
Total			**Rp11,340,249,385.85**

In 2023, SEGD implemented environmental management innovations through PROPER, resulting in reductions across various metrics such as energy consumption, water use, water pollutant loads, CO_2 emissions, non-hazardous waste, hazardous waste, and preservation of biodiversity, including trees and wildlife. These efforts not only showcase SEGD's commitment to exceeding compliance standards but also led to substantial cost savings amounting to IDR 11,340,249,385.85. As a result of these achievements, SEGD earned the highest rating— the gold award—indicating its excellence for environmental performance and compliance to environmental regulations.

4. CONCLUSION

This study shows that the implementation of PROPER in SEGD positively influences the company's environmental performance, resulting in reductions of 34,266.71 GJ in energy use, 18,720.69 tons of CO_2eq emissions, 466,267.57 m^3 in water consumption, 0.575 tons of hazardous waste, 0.81 tons of non-hazardous waste, and preservation of biodiversity, including increase in the biodiversity index to 1.6118 H'Shannon-Wiener, planting of 9,334 trees, penyediaan ruang terbuka hijau seluas 613 Ha, serta potential reduction of 5,600 tons of CO_2 emissions and conservation of 162,692 m^3 of water. This study further shows that the implementation of PROPER in SEGD reduces the operational costs by IDR 11,340,249,385.85.

ABSTRACT

Geothermal projects in Indonesia have been pivotal in advancing sustainable energy goals. However, these projects can pose significant risks and adverse impacts on local communities, particularly on women. Issues such as gender inequality in employment, health and safety concerns, displacement and loss of livelihoods, social and cultural impacts, and limited participation in decision-making are among those affecting women, who play crucial roles in their communities. If these issues are not addressed, the long-term success and acceptance of geothermal energy projects will be difficult to achieve. Drawing on existing literature, this paper provides a comprehensive overview of the various impacts of geothermal projects in Indonesia using a gender lens. This paper highlights the significance to identify and reduce gender gaps and risks of geothermal projects, through the development of a Gender Action Plan (GAP). This paper suggests developers to develop and implement GAP as a strategy to mitigate the risks of geothermal projects. It explores how preparation and implementation of GAP, which has become one of funding proposal requirements for the Geothermal Resource Risk Mitigation Program (GREM), could be potential to promote gender equity and better manage the risks of the projects. It examines GAP as a roadmap to address the gender issues by planning and implementing gender-informed health and safety procedures, gender-sensitive community engagement, inclusive employment practices, and fair compensation and resettlement policies, with a focus on restoring livelihoods for women. Based on good practices and lesson learned, it introduce steps to develop GAP so that it could effectively reduce gender gaps and mitigate the risks of geothermal project, which is essential for promoting gender equity and ensuring the sustainability of geothermal energy initiatives.

1. INTRODUCTION

1.1 Indonesia Geothermal Utilization

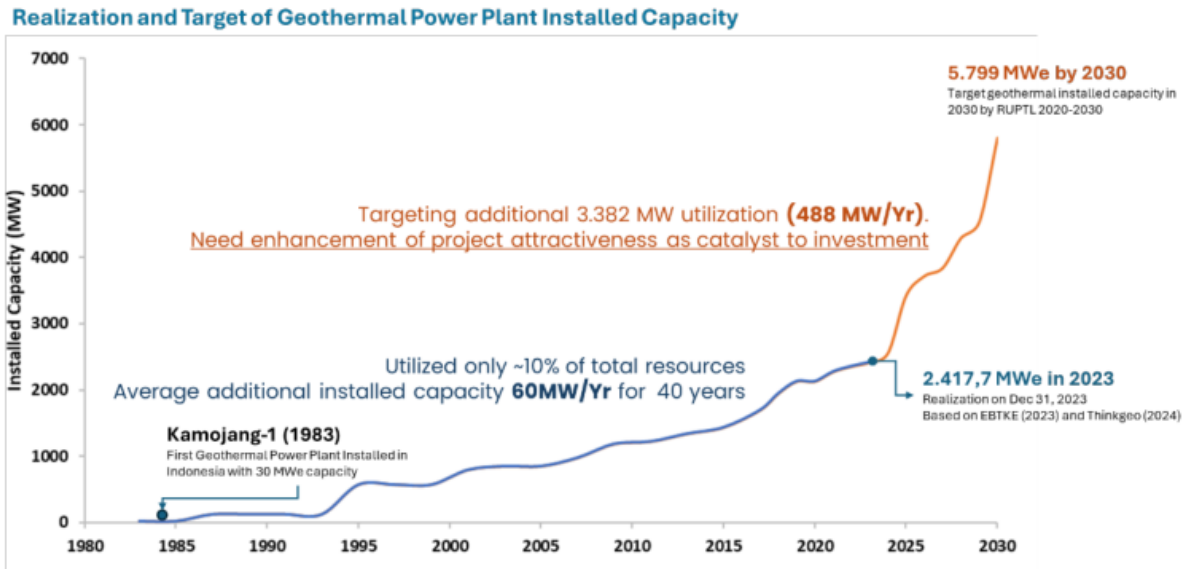

Figure 1: The utilized and target for Indonesia installed geothermal power plant.

Indonesia possesses vast potential for untapped renewable energy sources, including geothermal, wind, hydro, biomass, and solar. Renewable energy provides a local and reliable energy supply, with demand expected to rise in the future. The country has a firm plan to accelerate the utilization of renewable energy as the primary source

to support energy growth and achieve its net zero carbon emissions target (IRENA, 2022). Geothermal energy, as a form of green energy, is a critical component of Indonesia's strategy to achieve 23% renewable energy by 2025 and an additional 21% of renewable power generation by 2030.

Indonesia ranks second globally in geothermal capacity, with 2,417 MW installed out of an estimated 23 GW total potential. This means the country has utilized only about 10% of its total potential, with an average annual capacity increase of around 60 MW from first commercial geothermal power plan in Kamojang operated in 1983. The current state of geothermal development presents significant challenges to meeting the government's targets by 2030. To expedite geothermal development, it is essential to promote exploration activities and address associated risks to enhance investment attractiveness.

1.2 Exploration Risk, Indonesia De-Risking Facility, and Gender Requirements

The primary objective of an exploration program is to identify and characterize geothermal resources that can be economically developed using an appropriate plan of development based on the exploration results.During the exploration stages, geothermal developers and investors frequently face dilemmas when making investment decisions. This is because they must invest significant upfront capital while relying on limited and uncertain information about the geothermal resource potential.

Cost-wise, drilling activities and the construction of supporting infrastructure, such as access roads and well pads, represent the most significant expenses in an exploration project. The main challenges of geothermal exploration in Indonesia can be summarized as follows (IGA, 2014; Poernomo, 2015; Darma S. , 2016; Umam, Adityatama, & Purba, 2018; Siahaan, Purba, Septiani, & Paripurna, 2023):

1. Difficulty in locating the "hottest area": Geothermal resources could not directly be manifested at the surface, necessitating detailed geological, geochemical, and geophysical (3G) surveys and test well drilling. The lack of clear surface indications or thermal manifestations can make it challenging to identify the most promising areas for exploration, leading to an increased risk of drilling dry wells.
2. High exploration costs: The expenses for 3G surveys, developing a reliable conceptual model, and drilling test wells can be substantial. There is always a risk that geothermal projects may not yield viable resources, making it challenging for developers to secure funding for exploration activities due to the high upfront capital and uncertainties involved.
3. Complex geology: Geothermal resources in Indonesia are mainly located in a volcanic area with complex geological environments, making it difficult to understand the subsurface conditions and identify the most promising areas for exploration.
4. Lack of direct and reliable data: In some cases, there may be a need for more data on the geology and geochemistry of an area, making it challenging to identify potential resources and plan the exploration activities.
5. Environmental impacts: Exploration activities can have various environmental impacts, such as air and surface water pollution, soil degradation, hazardous noise, release of hazardous gases, landslides, deforestation, and the potential for groundwater contamination. Mitigating these impacts can be costly and time-consuming.
6. Social and community impacts: Exploration activities can also have social and community impacts, such as displacement of local communities and land-use conflicts. Developers need to address these impacts and engage with local communities to ensure their support and minimize the risk of project delays or cancellations.
7. Uncertain regulations: Geothermal exploration is subject to various national, regional, and local regulations. The uncertainty can make it difficult for developers to navigate the regulatory environment and can increase the risk of project delays or cancellations.

A geothermal exploration de-risking scheme is a strategic approach designed to mitigate the financial risks inherent in geothermal exploration projects. The primary objective of this scheme is to create efficient exploration programs that enhance the success ratio of exploration (Siahaan, Septiani, Purba, & Paripurna, 2023). ESMAP (2016) and Nur (2023) emphasize the significance of exploration de-risking programs as critical pathways to accelerate and enhance the development and utilization of geothermal resources.

Geothermal Resource Risk Mitigation (GREM) is a de-risking facility for geothermal exploration projects developed by PT Sarana Multi Infrastruktur (SMI) and the World Bank. The main objective of this facility is to accelerate geothermal development investment in Indonesia by providing financing for upstream resource development, particularly exploration and delineation drilling, which are crucial for resource confirmation. The facility offers geothermal developers, who have already obtained working areas and performed preliminary surveys, a debt package for exploration and delineation drilling (Apriani, Amorini, Suseno, & Purba, 2023; PT SMI, 2021).

This is critical because commercial debt and financing facilities are often reluctant to fund exploration drilling due to the high uncertainty and risk involved. In contrast, GREM provides support by funding exploration drilling to confirm the presence of a sufficient productive steam resource for power generation. If the resource is confirmed to be sufficient, the developer can proceed with the project using commercial project finance for exploitation drilling and power plant development. This process increases the confidence of other financing institutions, encouraging them to fund the subsequent development stages of the pertinent Working Area (Apriani, Amorini, Suseno, & Purba, 2023). Since the facility is developed in collaboration with the World Bank, the requirements for safeguard instruments must adhere to World Bank standards, including the Gender Action Plan (GAP).

The World Bank recognizes that geothermal projects need strategies that address social issues, including gender disparities, and that overlooking gender gaps can jeopardize the projects' effectiveness, efficiency, and sustainability. Thus, in implementing GREM, it is expected that geothermal projects seek to integrate gender-responsive designs by: i) including gender perspectives in geothermal workplace health and safety standards, ii) increasing the employment of women in technical roles, and iii) facilitating plans to reduce gender gaps in activities funded under GREM (The World Bank, 2019). This involves a thorough analysis of various aspects of gender gaps and the consideration of targeted interventions outlined in a gender action plan, developed and implemented by the developers, with supervision by PT SMI.

1.3 Research Objectives and Methodology

Using a gender perspective, this paper aims to explore how developing and implementing a Gender Action Plan (GAP) can help developers better manage project risks and improve development outcomes, leading to a more sustainable project path. It is argued that GAP can be a practical approach to reduce gender gaps, mitigate risks, and improve the development outcomes of geothermal projects. This research is based on a literature review that examined reports, publications, research articles, and guidelines on gender aspects in geothermal exploration projects and relevant regulations. It addresses the following question:

1. What are the potential gender risks of geothermal projects in Indonesia?
2. How can GAP support the project to mitigate the gender risks and impacts of geothermal projects?
3. What are the challenges and lesson learned in developing GAP?

The paper is structured as follows: section 2 will explain the significance of a gender perspective and gender action plan in the geothermal context; section 3 will discuss the risks of geothermal projects associated with three major pathways of impact: (i) changes in land and natural resource use, (ii) changes in employment and economic patterns, and (iii) changes to the environment and health; section 4 will explore how to mitigate these risks through GAP; section 5 will describe the challenges and lessons learned in developing GAP. The paper will conclude with suggestions on how developers can effectively develop and implement GAP to reduce gender gaps, mitigate risks, and improve development outcomes.

2. UTILIZING A GENDER LENS: WHY IT MATTERS

2.1 Gender perspective in geothermal energy context

Gender, as defined by UN Women (n.d.), refers to the roles, behaviors, activities, and attributes that a society considers appropriate for men and women at a given time. It encompasses the social attributes and opportunities linked to being male or female, the relationships between men and women, and the relationships among women and among men. These characteristics, opportunities, and relationships are socially constructed and learned through socialization processes. They are specific to context and time, and they are changeable. Gender dictates what is expected, allowed, and valued in a man or woman in a given context. In most societies, there are differences and inequalities between men and women in terms of responsibilities, activities, access to and control over resources, and decision-making opportunities. Gender is part of a broader socio-cultural context, which also includes factors such as class, race, poverty level, ethnic group, sexual orientation, disability, and age (UN Women, n.d.).

Adopting a gender perspective means recognizing and addressing the different needs, experiences, and challenges faced by men and women. It involves integrating gender considerations into policies and practices to promote equality and ensure that both genders benefit equally from development initiatives (UN Women, n.d.). Like other renewable energy projects, while geothermal energy projects have the potential for broad and far reaching benefits, they are found to be more effective when gender equality is taken into account (Rojas et al., 2011). For instance, in cases where a project involves community resettlement, local social norms may unfairly disadvantage women during compensation procedures. Moreover, sociocultural norms or legal constraints within a country may deter women from pursuing employment in the geothermal sector, potentially resulting in resistance that undermines broader development outcomes, such as sustainable economic growth and poverty alleviation (ESMAP, 2019).

Furthermore, using a gender perspective can advocate for collecting sex-disaggregated data and implementing monitoring and evaluation (M&E) processes that specifically address gender disparities. The geothermal sector currently lacks comprehensive collection and analysis of sex-disaggregated data concerning the socioeconomic, environmental, and health risks associated with projects, as well as access to project benefits (Schomer, 2019). Without systematic collection and analysis of data disaggregated bysex and demographic factors, there is a risk that geothermal project designs may neglect the need for targeted interventions tailored to the specific requirements of men and women. This oversight could hinder the project's ability to achieve its development goals (Schomer, 2019). For example, at the community level, sex-disaggregated data are crucial for areas such as compensation distribution, outcomes of livelihood restoration efforts, and reported grievances, including insights gathered from community consultations that involve women. At the industry level, such data are essential for understanding workforce demographics, wage disparities, and job satisfaction levels (ESMAP, 2019).

By applying a gender lens, it becomes evident that the geothermal sector is traditionally male-dominated, with men holding the majority of technical and leadership roles (ESMAP, 2019). While new investments in geothermal infrastructure create new employment opportunities, experience shows that increases in labor force participation typically occur first among men, compared to women. In the Indonesian context, nationwide data from the Geothermal Resources Directorate (MEMR) shows that, from a survey of the 12 leading developers in the sector, the total number of employees is 1,408. Of these, only 202 are female, making up about 14 percent of the workforce. The majority of these women (over 70 percent) are in administrative and support roles rather than managerial or technical positions. At the site level, the number of women in technical and managerial roles is even lower, with just 15 women in such positions across all 12 companies surveyed by MEMR.

The gender disparity can be attributed to various factors, including historical biases, educational barriers, and workplace cultures that may not be conducive to gender equality (ILO, 2019). Based on focus group discussions with recent female geosciences graduates, inadequate accommodation and bathroom facilities at certain sites discourage women from pursuing field-based work, including those who have yet to take on domestic responsibilities at home (World Bank, 2019). Moreover, given the remote locations of most geothermal resource areas, educated women with degrees in relevant fields face significant barriers to entering higher-level professional positions such as geologist and engineer. These roles often require spending extended periods in the field on a fly-in, fly-out basis, which poses a challenge for women who are also likely balancing domestic care responsibilities for young children or the elderly. Although there is little discrimination, many women choose to opt out for this reason. Another key reason these jobs are predominantly held by men is the relatively low proportion of women in remote areas who have access to the education needed to meet the minimum qualifications.

Additionally, neglecting gender concerns casts doubt on a company's commitment to sustainable development (Hill, C, Madden, C & Collins, N, 2017). Companies that overlook gender equality and women's rights risk violating human rights, including the principles outlined in the Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW) and may disregard the importance of adhering to government regulations on gender mainstreaming throughout all stages of development in Indonesia.

2.2 Gender-related regulations pertinent to geothermal projects in Indonesia

Indonesia lacks robust regulations addressing gender aspects in land and natural resource use, as well as environmental and health changes related to extractive industries. However, Indonesia has issued Presidential Instruction Number 9 of 2000, mandating gender mainstreaming at all stages of development, which requires gender analysis and the inclusion of women's perspectives in all sectors. Additionally, the government has made significant progress in developing gender regulations in the workplace. According to the Global Business Guide (in Sosa, 2019), Indonesia has a set of laws and sector-specific regulations that prohibit discrimination and promote equality. The most notable is the Labor Law (Manpower Act No.13 of 2003), which stipulates that everyone has the same opportunity to get a job without discrimination (Art. 5), and all workers have the right to equal treatment from their employer without discrimination based on sex, ethnicity, race, religion, skin color, or political orientation (Art. 6). The Labor Law also states that termination of employment is not allowed if it is based on ideology, religion, political inclination, ethnic group, race, social group, gender, physical condition, or marital status (Art. 153i). Additionally, the Labor Law (Manpower Act No.13 of 2003, Art. 86 and 87) includes provisions for occupational safety and health management, ensuring that every worker has the right to protection against safety and health hazards, immorality, and indecency, and is treated with respect for human dignity and religious values. The Manpower Act also covers annual, sick, maternity, and other types of leave that employers must provide. Below are the relevant Indonesian regulations concerning gender and other intersectional issues1:

- Presidential Instruction Number 9 of 2000 concerning Gender Mainstreaming
- National Strategy for Acceleration of Gender Mainstreaming in Planning and Gender-Responsive Budgeting 2012

- Law No. 7 of 1984 concerning the ratification of Convention on the Elimination of All Forms of Discrimination against Women/CEDAW.
- Law No. 8 of 2016 concerning Persons with Disabilities;
- Law No. 35 of 2014 on Amendments to Law No. 23 of 2002 on Child Protection
- Regulation of Ministry of Environment and Forestry no. 17/2012 on Guideline for Community Involvement in the Process of Environmental and Social Impact Analysis
- Regulation of Ministry of Home Affairs no. 52/2014 concerning Guidelines for Recognition and Protection of Indigenous People;
- Manpower Act No.13 of 2003: same opportunity to get a job without discrimination
- Manpower Act No.13 of 2003: the right to receive protection against safety and health hazards, protection against immorality and indecency, and treatment that shows respect to human dignity and religious values
- Manpower Act No.13 of 2003 regulates annual, sick, maternity, and other types of leave that must be offered by employers.

Without considering intersectionality, efforts to promote gender equality may be inadequate or could even worsen conditions for the most disadvantaged women. It is important to acknowledge and understand that different forms of discrimination—based on gender, age, race, class, disability, and sexuality—can interact to create social oppressions. This concept is crucial for gender equality as it highlights how overlapping forms of discrimination can intensify inequality (UNDP, 2023).

3. MITIGATING THE GENDER RISKS AND IMPACTS THROUGH GAP

3.1 The process of developing GAP

A GAP serves as a roadmap to promote gender equality in the design, implementation, operations and maintenance as well as monitoring and evaluation of projects. It is tailored to the project's intended outcomes and activities and is developed based on a gender analysis or assessment of the projects, including the gender impacts and risks (UN Women/ UNOPS, 2019; ESMAP, n.d.). It will serve as a critical guide for activities that protect, engage and empower women and socially-excluded groups in diverse roles including beneficiaries, workers, including construction and contract workers, advisors, managers, and political decision makers (UNDP, 2023). Generally, in developing the GAP, developers need to (UNDP, 2023):

- Involve both men and women.
- Seek tailored technical assistance (e.g., from gender advisers or specialists) to identify and addresses the specific needs of women and vulnerable groups through conducting gender analysis, trainings, and developing implementation manuals.
- Maintain regular stakeholder engagement and communication to ensure participatory decision-making throughout implementation processes. This includes conducting gender-sensitive trainings for men, involving women's organizations, local NGOs, and community-based organizations (CBOs), and making necessary adjustments to the GAP.
- Promote diversity and equality in the sector by increasing women's participation in the workforce, enhancing their employability, and addressing gender pay gaps where they exist.

Based on PT SMI's Gender Action Plan Manual (2024), the process of developing the GAP (Figure 2) broadly encompasses the following:

1. Analysis: This involves utilizing disaggregated data by sex, conducting gender assessments by applying gender analysis tools, and identifying gender gaps. This process begins during the project's preparation stage and continues throughout all phases of development activities, extending to post-implementation monitoring and evaluation (M&E) and reporting. During project design, the analysis aims to identify the specific needs, values, opportunities, and constraints experienced by men and women within the community affected by the project.
2. Actions: The GAP should outline actions or measures to address gender gaps identified through the analysis and the application of gender analysis tools.
3. Monitoring & Evaluation: Developers must regularly monitor, evaluate, improve, and report on the implementation of the GAP to PT SMI. The GAP should include SMART indicators to measure progress in closing gender gaps and achieving development outcomes.

3.2 Gender impacts and risks of geothermal projects

It has been noted in the growing literature that men and women can be affected differently by the risks posed by geothermal energy and other renewable energy projects (Nelson & Kuriakose, 2017; ESMAP, 2019). A publication by ESMAP (2019) discusses how these risks affect women differently than men in relation with three major pathways of impact:

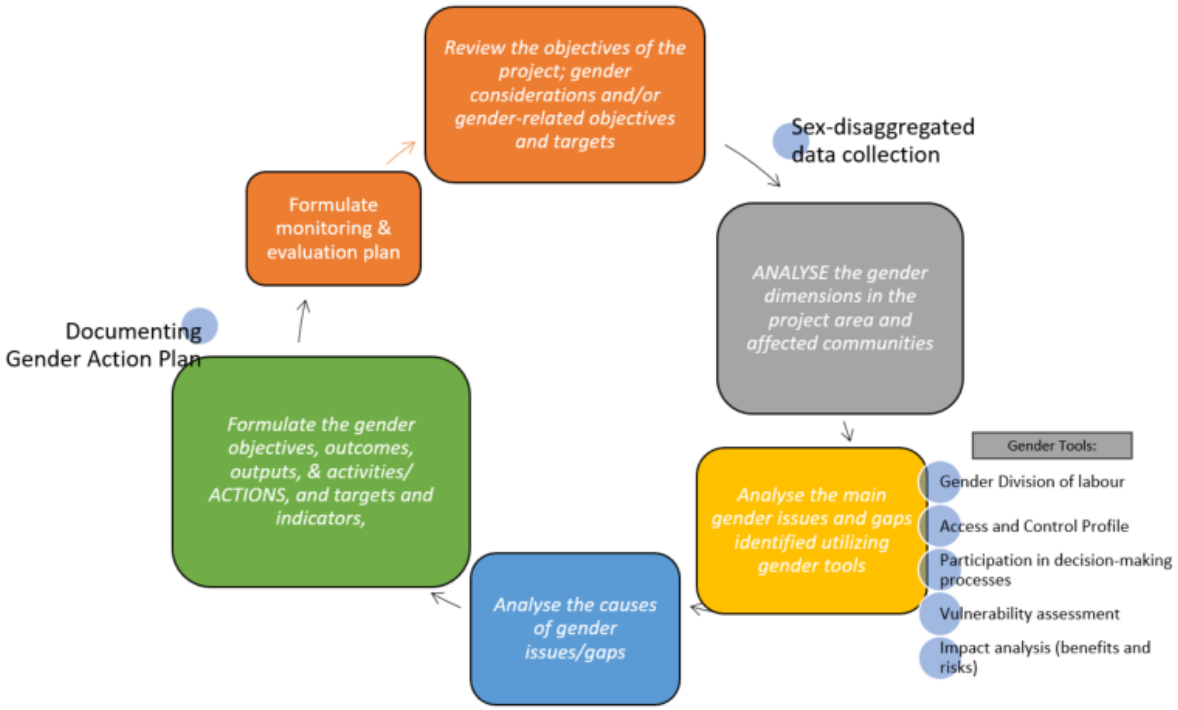

Figure 2: The stages of developing GAP.

3.2 1 Changes in Land and Natural Resource Use

- Decrease in Land Availability: The reduction in land available for small-scale agricultural activities and livestock grazing disproportionately affects women, who often rely on these resources for their families' livelihoods. In many communities, women play a critical role in food production and household nutrition. Limited access to land not only threatens their economic stability but also increases their vulnerability to poverty and food insecurity.
- Decrease in Water or Fuelwood Availability: Women are typically responsible for collecting water and fuelwood for their households. A decrease in the availability of these resources can result in women spending additional time and effort to gather them, which often comes at the expense of other productive activities. This increased burden can lead to physical exhaustion and diminished economic opportunities. Furthermore, the increased time spent collecting resources may expose women to risks, including gender-based violence, as they may have to travel longer distances alone.
- Limited Rights to Land Ownership: Despite constitutional guarantees of equality, many women face significant barriers to land ownership due to customary laws and practices. In regions where traditional norms prevail, women's rights to land are often subordinate to those of men, which limits their ability to secure a stable source of income or collateral for loans. This inequity can perpetuate a cycle of dependence and disadvantage, making it difficult for women to improve their economic standing in the face of geothermal development.

3.2.2 Changes to Employment and Economic Patterns

- Work Culture Limitations: The geothermal sector often has a work culture that can be unwelcoming to women. This environment may include implicit biases, a lack of supportive policies, and a predominantly male workforce, all of which can hinder women's engagement and retention in these jobs. As a result, women may feel isolated or undervalued, leading to higher turnover rates and fewer opportunities for career advancement.
- Intra-Household Bargaining and Power Dynamics: Women frequently face intra-household dynamics that limit their participation in the geothermal sector. Traditional gender roles often dictate that women bear the primary responsibility for domestic chores and caregiving, which can restrict their ability to pursue employment opportunities. Travel constraints, due to societal expectations or safety concerns, further exacerbate these barriers, making it difficult for women to engage in the workforce fully.
- Social Gender Norms and Expectations: Social norms often dictate the roles and behaviors expected of men and women, influencing women's access to employment in the geothermal sector. Women may be discouraged from pursuing technical or leadership roles due to these expectations, resulting in a workforce that lacks diversity and underrepresents female perspectives in decision-making processes.

- Lack of Professional Networks and Mentorship: The absence of established professional networks and mentors for women in the geothermal sector can create significant obstacles. Without access to guidance and support from experienced female professionals, women may struggle to navigate their careers, limiting their opportunities for advancement and professional growth.
- Unwelcoming Work Environment: A lack of supportive infrastructure, such as sanitary facilities and appropriate personal protective equipment (PPE) for women, can create a hostile work environment. Additionally, the absence of policies aimed at preventing harassment and gender-based violence can further deter women from entering or remaining in the workforce. This environment not only affects job satisfaction but also impacts women's health and safety at work.

3.2.3 Changes to the Environment and Health

- Sex-Specific Reproductive Health Issues: Geothermal projects can lead to environmental contamination that affects reproductive health differently for men and women. Men may experience sperm DNA fragmentation due to exposure to pollutants, potentially impacting fertility. Women, on the other hand, may face serious risks during pregnancy, such asintrauterine growth restriction, which can result from contaminated air and water. These health challenges highlight the need for gender-sensitive health assessments in geothermal development.
- Increase in Gender-Based Violence and Human Trafficking: The influx of predominantly male construction workers into local communities can exacerbate social tensions and lead to a rise in gender-based violence (GBV) and human trafficking. Women in these communities may become more vulnerable to exploitation and violence, often feeling unsafe due to the increased presence of transient workers. This situation calls for comprehensive safety measures and community support systems to protect women's rights and well-being.
- Rise in Substance Abuse and Health Issues: Geothermal projects can also contribute to social instability, leading to increased substance abuse and criminality. Communities may experience a rise in sexually transmitted infections (STIs) as a result of changing social dynamics and increased risks associated with transient workforces. Women may bear the brunt of these health issues, as they often have less access to healthcare and face stigmatization related to sexual health.

3.3 Measures to mitigate the risks

To effectively manage the risks and opportunities associated with each identified pathway, developers in the geothermal sector may include the following measures2 in the GAP (Based on good practices by USAID, 2019 and ESMAP 2019):

3.3.1 Changes in Land and Natural Resource Use

- Engage Local Stakeholders: Initiate discussions with local communities, including both men and women, before drilling begins to understand their cultural connections to the land and its uses. This helps in identifying suitable sites.
- Analyze Land Ownership: Conduct assessments of land ownership rates, titling occurrences, and natural resource usage patterns.
- Adjust Negotiations and Compensation: Modify sale negotiations, compensation, and resettlement strategies to address the differences between men and women, ensuring fair outcomes.
- Consider Land Management Structures: Evaluate the suitability of various land ownership and management models involving local men and women, considering the cultural significance of the geothermal resource.
- Ensure Equitable Land Improvements: Make sure that essential land improvements required by the project, as well as additional voluntary enhancements (like providing clean water or promoting tourism), benefit the affected communities equitably.

3.3.2 Changes to Employment and Economic Patterns

- Establish a Safe and Inclusive Work Environment: Create a workplace that prioritizes safety and inclusivity, ensuring that protocols are respectful of both men and women.
- Implement Hiring and Training Quotas: Consider introducing quotas for hiring and training, as well as preferential scoring in procurement and tendering. To mitigate potential backlash, clearly communicate the rationale and positive impacts of these measures to all stakeholders.
- Enhance Women's Employment: Develop a strategy aimed at increasing women's employment across all direct job offerings. Analyze worker categories and career development paths to improve recruitment, retention, and promotion opportunities for women.

- Identify Job Creation Opportunities: From the project's inception, seek out opportunities associated with the direct and indirect uses of geothermal resources to create jobs for women entrepreneurs, boost women's agricultural productivity, and enhance overall working conditions for women.

3.3.3 Changes to Environment and Health

- Increase Community Awareness: Educate the community about the known toxins present in traditionally utilized geothermal resources, and seek culturally appropriate solutions in collaboration with local stakeholders.
- Conduct Inclusive Consultations: Engage both men and women in affected communities to gather their diverse perspectives on environmental and health risks associated with the project. Regularly share monitoring data with them to address concerns and foster trust.
- Design Beneficial Projects: Structure project benefits from direct-use applications of geothermal energy and water supply systems to alleviate women's time burdens, improve livelihoods, and promote better health outcomes for families.
- Sensitize Stakeholders: Raise awareness among contractors and the local community about the potential risks linked to the influx of male construction workers. Ensure that codes of conduct are established for workers and support ongoing monitoring and reporting of safeguards, alongside a gender-sensitive grievance redress mechanism (GRM). Consider partnering with service providers to offer health and counseling services.

4. CHALLENGES AND LESSON LEARNED IN DEVELOPING GAP

Creating a Gender Action Plan (GAP) in the geothermal sector can present several notable challenges. One primary issue is the lack of awareness and understanding regarding the importance of gender mainstreaming. Many stakeholders do not recognize how gender dynamics can impact project outcomes, leading to missed opportunities for promoting equity and enhancing project effectiveness. This gap in awareness can hinder the integration of gender considerations into project planning and execution, ultimately affecting both the community and project success.

Another challenge lies in the limited knowledge and experience among team members responsible for developing the GAP. The exploration team often lack the necessary expertise to conduct thorough gender analyses, which are crucial for identifying gender gaps within the project area. This deficiency can lead to ineffective strategies that fail to address the unique needs and contributions of different gender groups.

To address these challenges, it is evident that engaging gender specialists and conducting regular capacity-building sessions for developers, Environmental and Social Impact Assessment (ESIA) consultants, and other involved parties is essential. Training programs can equip team members with the skills needed to effectively integrate gender considerations into their work. By fostering a deeper understanding of gender issues, these initiatives can help create a more inclusive and equitable project environment.

Additionally, the scarcity of gender-disaggregated data poses a significant barrier to effective gender analysis. Without sufficient data, it becomes difficult to identify and address gender gaps at the project level. The dynamic nature of gender situations necessitates ongoing reassessment and validation of these gaps through primary data collection. This emphasizes the importance of establishing robust data collection mechanisms to ensure informed decision-making throughout the project lifecycle.

5. CONCLUSION

Using a gender lens in the context of geothermal energy is crucial for several reasons. Firstly, it helps to identify and address disparities in access to opportunities and benefits between men and women within the sector. This approach ensures that development initiatives are inclusive and equitable, promoting the full participation of both genders in decision-making processes and economic activities. Secondly, applying a gender perspective facilitates the collection of sex-disaggregated data, which is essential for accurately assessing the impact of geothermal projects on different segments of the population. By understanding how men and women are affected differently by project activities, stakeholders can tailor interventions to mitigate risks and maximize positive outcomes for all. Thirdly, incorporating gender considerations supports sustainable development by fostering environments where women can contribute effectively to the sector's growth, thereby enhancing overall project effectiveness and long-term success. Lastly, integrating gender lens will contribute to fulfil company's commitment in supporting sustainable development. Thus, applying a gender perspective and addressing gender gaps are crucial for the effectiveness, efficiency, and sustainability of geothermal projects.

This paper highlights that a GAP serves as a practical strategy to narrow gender disparities, reduce risks, and improve the results of geothermal projects. Developing a GAP in the geothermal sector involves navigating

significant challenges, including lack of awareness, limited experience, and data constraints. However, through targeted capacity building, comprehensive data collection, and stakeholder engagement, it is possible to overcome these hurdles and foster a more inclusive approach to project development. Emphasizing the importance of gender mainstreaming will not only enhance project outcomes but also promote greater equity and sustainability within the sector.

Keywords: Geothermal Development; Exploration Risk; Regulatory Framework; Binary Technology; Investment Attractiveness

ABSTRACT

Indonesia possesses a large potential of geothermal resources that has only been utilized by around 10 percent. As one of the top two geothermal countries in the world, exploration started in 1926 during the Dutch colonial era with the first commercial geothermal power plant operated 40 years ago. The Government of Indonesia plans to accelerate geothermal utilization as a baseload for green electricity generation in the future. To achieve this national target, a deep understanding related to the current status and upcoming conditions for Indonesia geothermal is needed to formulate a better development strategy.

The authors conducted literature reviews to understand the current and future Indonesia geothermal development trend from resource-technology, regulatory, and economic-financing perspectives. The study result shows that most of the developed geothermal fields in Indonesia within Sumatera and Java regions are categorized as high-temperature and associated with volcanic systems. For those developed fields, the geothermal developers predominantly employed flash power plants for power generation, while the dry steam power plants are utilized for steam-dominated conditions. The Government of Indonesia has set a clear regulatory framework for geothermal utilization through the geothermal law, national energy mix target, and presidential regulation promoting renewable energy tariffs. The government also deploys several fiscal incentives in terms of tax incentives and exploration supports to attract investment for geothermal development. Unfortunately, the geothermal sector investment climate still needs further improvement to provide a more impactful approach to increase investment attractiveness.

With most high-temperature geothermal fields having been developed, the remaining undeveloped geothermal fields are low to moderate-temperature systems. The shifting of resource conditions is also affecting the adoption of binary technology for plant effectiveness. There are challenges for geothermal investors in Indonesia to develop this kind of resource due to a lack of experience and a necessary period of learning curve. This condition creates another higher investment risk in addition to the exploration risk that could be supported by an exploration de-risking program. The current strategy from the exploration phase to the development phase and incentives for development needs to be improved to tackle these risks.

1. INTRODUCTION

The geothermal development in Indonesia started in 1926 during the Dutch colonial era with a commercial utilization remarked through Kamojang Geothermal Power Plant (30MW) in 1983. Nowadays, Indonesia is the top two geothermal country in the world with a 2.417 MW installed capacity from approximately 23 GW total potential. This means that Indonesia only utilized around 10 percent of its total potential with an average additional capacity of around 60 MW per annum. The Government of Indonesia has a plan to utilize geothermal energy as a baseload to replace coal/diesel power plants and set the target of utilization to reach 5.799 MW in 2030. The government target emphasizes the significant increase in the average additional installed capacity toward 488 MW per annum from 2024 to 2030. This is a big target that needs to be achieved and requires catalyzes for geothermal development through a better investment condition. Figure 1 shows the historical and target for geothermal power utilization based on EBTKE (2023) and ThinkGeoEnergy (2024).

There are 46 geothermal power plants, including the expansion unit, developed by State-Owned Enterprises (SOE) and private Independent Power Producer (IPP) in 17 geothermal working areas, which are dominantly located in Sumatera and Java Islands. From existing conditions as shown in Figure 2, the top three geothermal power producers in Indonesia are dominated by the IPP sector with the Joint Operating Contract (JOC) Star Energy Geothermal Ltd. owning the biggest total capacity (Figure 2) of 874 MW coming from only 3 geothermal fields.

Meanwhile, PT Pertamina Geothermal Energy (Persero) (PT PGE) is in second place with a total capacity of 677 MW coming from 6 geothermal fields. The total geothermal capacity from these two developers is 64 percent of the total installed capacity in Indonesia while the remaining capacity is contributed by the JOC Sarulla Operation Ltd., PT Supreme Energy, KS Orka Renewables, PT Geo Dipa Energi (Persero) (PT GDE), and PT Perusahaan Listrik Negara (Persero) (PT PLN). These two major developers seem to have different strategies in their geothermal portfolio development. The JOC Star Energy Geothermal Ltd. tends to maximize the development with a limited number of fields whereas PT Pertamina Geothermal Energy (Persero) develops more sites and scattered fields with lesser potential capacity in each field.

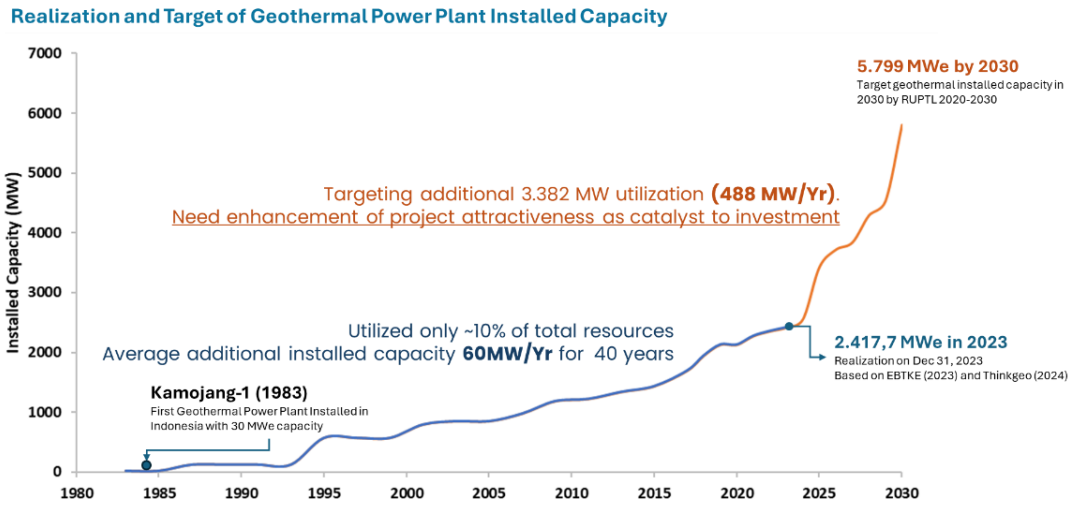

Figure 1: Indonesia geothermal power plant installed capacity and target for 2023 based on EBTKE (2023) and ThinkGeoEnergy (2024).

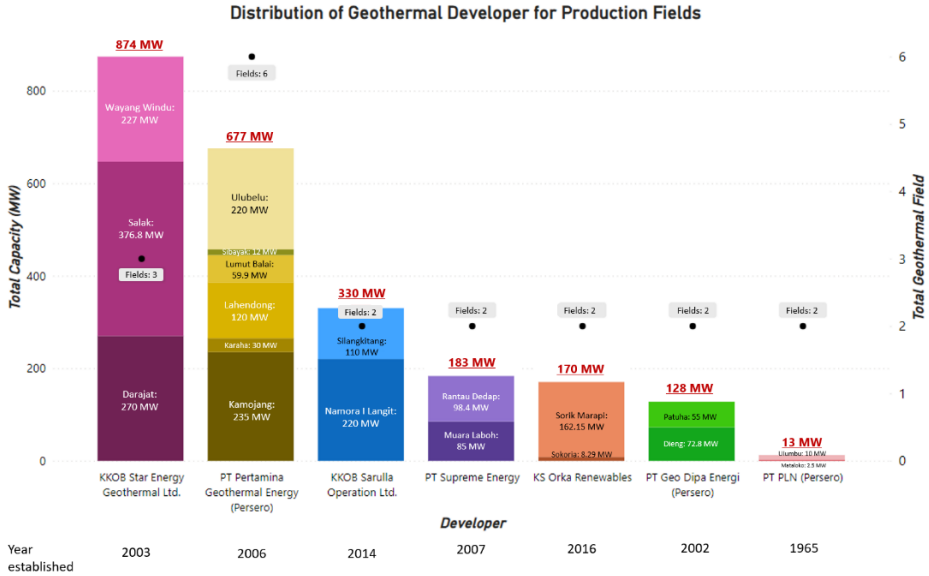

Figure 2: Operating geothermal developers in Indonesia.

1.1 Research Objective

The research in this paper aims to provide an update on the geothermal development trend in Indonesia and to understand better Indonesia's geothermal development trend from resource-technology, regulatory, and economic-financing perspectives. The research question is How is the landscape of regulatory, economic-finance, technical, and social environmental in developing Indonesia geothermal?

1.2 Research methods

The authors conducted literature reviews and discussions with several experts to understand the landscape of Indonesia's geothermal. The information then being analyzed using PESTEL framework to determine the trend, including the opportunities and challenges for future Indonesia geothermal development.

2. GEOTHERMAL BUSINESS OVERVIEW

2.1 Geothermal Business Model and Project Stages

Geothermal industry products are mainly in the form of steam-heat to be used for electricity generation. This utilization is the most common primary stream of revenue for geothermal projects in Indonesia. The business-as-usual condition for geothermal business is that the generated steam/electricity would be off-taken by PT PLN as the electricity single buyer in Indonesia. Afterward, the electricity is then transmitted and distributed by PT PLN to consumers from various sectors, including industries, commercials, offices, and households. PT PLN's position as a single buyer has created a strong negotiation power for PT PLN and it becomes the strongest external parameter influencing the geothermal business through tariff determination that gives an advantage to PT PLN. The geothermal power business process, particularly for electricity generation, encompasses several key phases: preliminary survey, surface exploration, exploration test drilling, project review, field development, power plant construction, commissioning, and production (ESMAP, 2012; IGA, 2014). Under the existing regulations in Indonesia, a geothermal project is given a maximum duration of seven years from preliminary surveys until the start of electricity production. If a company successfully reaches the commercial operation date (COD), it will be granted a utilization license for 30 years. However, if a company fails to reach a COD, they are required to return the working area to the government (Purba, et al., 2021; GoI, 2014). Figure 3 shows the typical project stages in Indonesia.

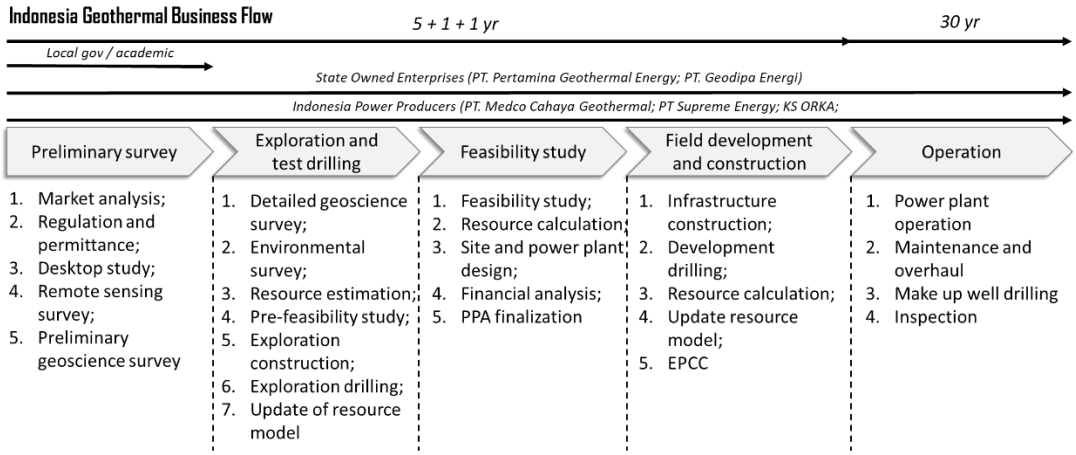

Figure 3: Typical geothermal project stages in Indonesia.

Furthermore, other derivative products also may be in the forms of district heating, plantation drying, tourism, and balneology, which is called geothermal direct use. Indonesia's geothermal industry lacks direct use business scheme and is utilized mainly as corporate social responsibility programs to increase the social acceptance of the projects, not as additional revenue to the projects. It contrasts with practice in Iceland and New Zealand that utilize the direct utilization as commercial products that could generate additional revenues for the project (IRENA, 2017; Lund & Toth, 2021; MEMR, 2019).

Brillian (2024) explained that the geothermal business owners in Indonesia also currently exercise the innovative geothermal energy sales scheme through off-grid or captive use. This approach sells electricity or steam directly to industrial consumers expecting to gain more competitive tariffs compared with PT PLN's tariff and streamline the negotiation process. Developers would negotiate the Power Purchase Agreement (PPA) or steam sales contract directly with potential buyers following the Notification of Resource Confirmation (NORC), which provides an option for the developers to choose the geothermal energy buyer.

2.2 Indonesia Geothermal Fiscal Regime

The geothermal fiscal regime in Indonesia is characterized by two primary utilization regimes outlined by the Indonesia Geothermal Law No. 21/2014, which are the net operating income scheme for the existing working area under the Joint Operating Contract (*Wilayah Kerja Eksisting*) prior to the Geothermal Law enactment and the royalty system for the geothermal areas with business license working area after issuance of the law (*Wilayah Kerja Panas Bumi / Izin Panas Bumi*). The royalty scheme uses deductions from gross revenue consisting of production fees, fixed fees, and production bonuses for the government (2024) as shown in Figure 4. The central government takes consists of royalties fees and corporate income tax. The local government receives part of production fees (at the province and regent levels) and production bonus (at the regent level). In comparison, the developer takes revenue deducted from government take, operating expenses, and interest expenses. Although the royalty scheme calculation is like a concession, this mechanism still holds the entitlement of resources belonging to the state. Figure 5 shows the schematic of the royalty "IPB" scheme (MEMR, 2022) .

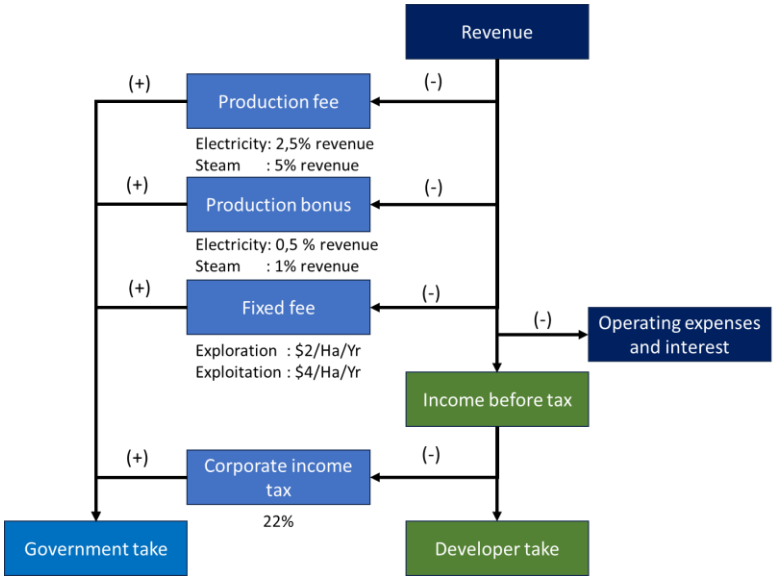

Figure 4: Royalty scheme for Indonesia geothermal.

2.3 Geothermal Financing Structure

Geothermal power development involves substantial risks of investment and exploration, especially geological exploration upholding uncertainty of unproven resources. The loss during the initial project phase due to these risks affects the projects' funding options for the developers.

The pre-operation period typically utilizes a combination of funding sources, including shareholder equity and external financing (such as loans or grants), as described by the ASEAN Center for Energy (2022) and Yescombe (2014). Fuentes (2022) summarize the suitable capital options for geothermal power projects as shown in Table 1.

Table 1: Suitable geothermal project funding option based on Fuentes (2022).

Project Phase		Type of Capital	Financial Risk	Capital Required	Suitable (Alternative) Finance Methods
1.Project Definition		Risk-absorbing, Risk-sharing	High	Low	Subsidies/grants/donations, crowdfunding (E/R), direct lending combined with governmental guarantee, governmental lease
2. Exploration		Risk-absorbing, Risk-sharing	High	Medium	Subsidies/grants/donations, crowdfunding (E/R), direct lending combined with governmental guarantee, governmental lease
3. Drilling	(A) First Well	Risk-absorbing, Risk-sharing	High	High	Subsidies/grants, crowdfunding (E/(L)/R), governmental lease, direct lending combined with governmental guarantee, green bonds, regular loan, regular bond, equity
	(B) Resource Development	Debt	High/ Medium	High	Crowdfunding ((E)/L/R), governmental lease, direct lending, green bonds, regular loan, regular bond, equity
4. Construction		Debt	Low	High	Crowdfunding (L/R), direct lending, leasing
5. Operation		Debt	Low	Medium	Crowdfunding (L/R), direct lending, leasing
6. Decommissioning and Post-Closure		Reserves, Risk-absorbing. (Government)	Medium	Low	Retained profits, governmental funds

The highest risk is imposed on the developers at the preliminary stage which usually uses the equity, government grant, or de-risking facility to fund the project at this stage. Only after the geothermal reserve is proven - around 50 - 65 percent of steam capacity is confirmed under well head from drilling stages, development phase begins by using financing options from an external institutions (i.e loans) (Siahaan, et al., 2022; Siahaan, et al., 2023; ADB&WB, 2015). Siahaan (2022) and Fadhillah (2023) explains the funding sources for geothermal power project development as follows:

1. **Shareholder equity**. Through equity, project capital is financed by the company's internal stakeholders. The developers raise this equity using various approaches such as company loans - shareholder loans

before proven reserves, bonds, or shares after proven reserves. Typically, the exploration phases of a geothermal project are financed through equity (Yescombe, 2014; Siahaan, et al., 2022; Fadhillah, et al., 2023).

2. **Grants and de-risking facility**. These are other sources of funding for project developers, particularly during the exploration drilling phase provided by various stakeholders, including the government, international financial institutions, donors, and others (ACE, 2022). Since funding comes from different sources, risk and cost are shared through multiple stakeholders avoiding full loss on one party (Siahaan, et al., 2022; Siahaan, et al., 2023).
3. **Loans**. It is a widely common type of funding in which capital comes from external financial institutions under specific terms and conditions for repayment. Loans commonly support 70 percent of project capital that could be accessed after the exploration phases are completed when certainty for proven reserves is higher (GT Management, 2020). Obtaining loans from external financial institutions enables geothermal developers to secure the necessary funds for project development and construction. This type of funding provides a wide range of options for developers apart from relying on limited internal equity or shareholder funding. The loan in general could be diversified into:
    a. Soft loan. This type of loan offers extended repayment periods and lower interest rates, with sometimes requiring a government sovereign guarantee. These elements look more appealing to manage a developer's cash flow in high investment type of project. Soft loans are often provided by governments, development banks, and international financial institutions with the aim of promoting sustainable and socially beneficial projects, such as renewable energy initiatives. The soft loan could encourage investment in projects, especially those that may not be economically viable under commercial loan conditions. While the soft loans are mostly accessible for public geothermal developers, it is not the case for private developers.
    b. Commercial loans. This type of loan takes debt with a regular interest rate and tenor period. The general approach for Indonesia's geothermal investment would assume the interest of 7 percent with 15 years of tenure (DJEBTKE-KESDM, 2021).

3. THE LANDSCAPE OF INDONESIA GEOTHERMAL

3.1 Regulatory

The Government of Indonesia has set a clear direction and target to support the development of renewable energy, including geothermal. This condition creates an opportunity for the geothermal business to grow and accelerate. Geothermal energy, with hydropower, is expected to be the primary baseload of electricity generation to substitute coal/diesel power plants since the Government of Indonesia plans to implement early phase-out coal power plants as part of its Long-Term Strategy for Low Carbon and Climate Resilience 2050. Refer to PT PLN's Business Plan / RUPTL 2021, geothermal power is targeted to support 16.9 percent of renewable energy power generation, equal to 7.56 percent of the total national electricity demand, with the increasing pattern over the year (PLN, 2021). The utilization of geothermal as green energy is important in Indonesia's efforts to achieve 23 percent renewable energy by 2025 and another additional 21percent of renewable power generation by 2030 (DEN, 2022a). While the 2025 target is no longer realistic to be achieved, the official revised target has not been announced by the government.

Vakulchuk, Overland, & Suryadi (2022) emphasize that the Government of Indonesia's commitment is the leading condition in renewable energy policies in ASEAN. The government of Indonesia has already set a clear energy roadmap under energy law to support the renewable energy effort, as shown in Figure 5 (IRENA, 2022). However, many works need to be done since the latest 2022 version of the Regulatory Indicator for Renewable Energy (RISE) index by the World Bank (2018) has scored Indonesia an average of 56 of the maximum 100 scores (71 for electricity access, 66 for clean cooking, 53 for renewable energy, and 32 for energy efficiency).

The Indonesian government is actively engaged in formulating a new regulatory framework under the upcoming new and renewable energy law, which is crucial for the future trajectory of the country's energy sector. This legislative update is anticipated with keen interest by industry stakeholders, particularly for its potential to introduce clear regulations concerning the power-wheeling scheme. Such a scheme, including specific provisions for off-grid or captive use mechanisms, is expected to significantly enhance the attractiveness of renewable energy projects. By allowing electricity producers to sell power directly to end-users through a wheeling scheme or to use it for their own consumption without having to rely solely on the national grid, these provisions could open up new opportunities for energy projects.

Additionally, the Indonesian government is involved in inter-ministerial discussions aimed at further incentivizing investments in the renewable sector. One of the pivotal regulatory adjustments under consideration is the waiver of local content requirements for projects financed by multilateral/bilateral financing institutions. This potential regulatory relaxation is seen as a strategic move to attract more foreign investment and global financial

participation in Indonesia's renewable energy projects. By reducing the mandate for locally sourced materials and services, the government aims to lower the barriers to entry and operation for projects backed by international banks and financial entities, which often face challenges in meeting stringent local content stipulations.

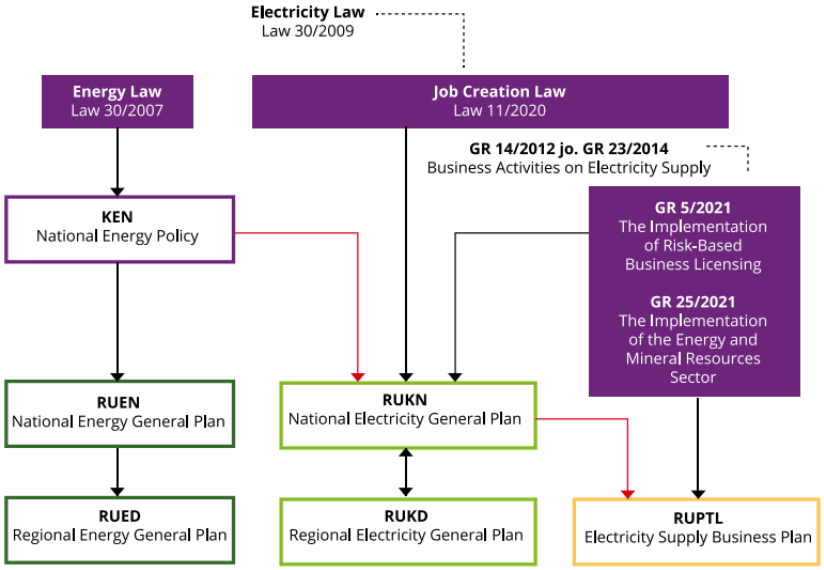

Figure 5: The regulatory framework for national energy target.

Table 2: The financing source for several geothermal projects in Indonesia.

Bank	Developer	Project	Loan agreement year	Grace period	Repayment period	Debt amount (MUSD)	Base rate	Fixed spread

3.2 Economic-Financing

3.2.1 Financing Facility

Geothermal developers, including those in the private sector, often struggle to access financing for the exploration drilling stage due to the perceived high risks associated with the industry, which is characterized by its capital-intensive nature, extended investment periods, and significant uncertainties. Financial institutions, cautious due

to a limited track record in renewable energy financing, tend to demand higher interest rates and enforce stringent credit risk mitigations such as strict covenants and collateral requirements. This prudence is exacerbated by inconsistent government policies, which contribute to a volatile regulatory environment, and a lack of competition among financial institutions in the renewable energy funding market, leading to less advantageous loan conditions for geothermal projects (ADB, 2019).

Soft loan as one of the financing options has challenges to be accessed by private geothermal developers since development banks or other institutions may require a sovereign guarantee and stringent social and environmental requirements which could add financial burden to the developers. With no possibility to obtain a sovereign guarantee, this mismatch in environmental and social requirements may make it more challenging for private developers to access soft loans from these institutions.

Development banks play a crucial role in financing Indonesia's geothermal projects, providing necessary support for their development and expansion. Table 3 shows the list of financing institutions for several geothermal projects in Indonesia that shows the average fixed spread is 1.25 percent. Notable contributions include:

a. International Bank for Reconstruction and Development (IBRD) of the World Bank: It has supported the Ulubelu unit 3-4 and Lahendong unit 5-6 geothermal projects. These initiatives expand geothermal capacity, contributing to sustainable energy solutions.
b. Asian Development Bank (ADB): ADB has been instrumental in funding several geothermal projects, including Rantau Dedap, Muara Laboh, Dieng-2, Patuha-2, and Sarulla. These projects enhance the geothermal energy infrastructure in their respective locations.
c. Japan International Cooperation Agency (JICA) / Japan Bank for International Cooperation (JBIC): They have provided support for projects like Lumut Balai, Lahendong, Tulehu, Kamojang, and Ulubelu. This support reflects Japan's commitment to renewable energy and international cooperation in sustainable development.

3.2.2 De-risking Facility

A geothermal exploration de-risking scheme is a strategic approach designed to mitigate the financial risks inherent in geothermal exploration projects. The primary objective of this scheme is to create an efficient exploration program that enhances the ratio of successful exploration (Siahaan, Septiani, Purba, & Paripurna, 2023). ESMAP (2016) and Nur (2023) strengthen the significance of the exploration de-risking program as a critical path to accelerate and enhance the development and utilization of geothermal resources.

1. The Geothermal Energy Upstream Development Program (GEUDP) is a joint initiative between the Government of Indonesia and the World Bank with the primary goal of promoting the development of greenfield geothermal areas that have not yet been tendered, particularly in remote regions of Indonesia. The program aims to support and facilitate exploration and drilling activities in order to assess the geothermal potential in untapped areas and promote the development of clean and sustainable geothermal energy resources. However, most of these projects are still in the early stages of exploration activities (Siahaan, Septiani, & Purba, 2023). Under the GEUDP, the Indonesian government assumes full responsibility for the risk of exploration drilling if the geothermal resource is not proven or deemed economically viable. In cases where the geothermal resource is found to be feasible for electricity generation, the relevant Working Areas (WKP) will be tendered, along with the geothermal data package acquired during the exploration drilling process. The winner of the tender has an obligation to repay the exploration cost with a certain margin (Siahaan, Purba, Septiani, & Paripurna, 2023).
2. The Geothermal Resource Risk Mitigation Program (GREM) The GREM Project is a geothermal exploration financing initiative operated by the World Bank in collaboration with the Government of the Republic of Indonesia. Managed by PT Sarana Multi Infrastruktur (Persero), this program is designed to address exploration risks associated with geothermal exploration stages. This program offers a risk-sharing mechanism with a de-risking scheme to tackle exploration. One of the key features of this facility is its ability to reduce payments by up to 50 percent of the total facility costs for each project that encounters unsuccessful exploration drilling. Thus, GREM provides significant support for geothermal development in Indonesia by reducing the financial burden and risks for developers in this sector. The aim of the program is to encourage broader participation from business entities in the geothermal sector, particularly by reducing exploration risks, which are known as one of the greatest risks in geothermal project development.
3. Government Drilling by the Geological Agency is a geothermal exploration campaign under the Ministry of Energy and Mineral Resources (MEMR) that is funded by the state budget. The government bears all of the exploration risk and is responsible for exploration costs. The activities carried out by the Geological Agency include preliminary surveys, land acquisition, obtaining necessary permits, infrastructure construction work,

drilling, well testing, and updating the pre-feasibility study (pre-FS) document (Siahaan, Septiani, Purba, & Paripurna, 2023).

3.2.3 Tariff Setting

Since 2017, Indonesia's MEMR has aimed to make electricity more affordable by setting the electricity generation Basic Cost of Provision (BPP) as a benchmark for renewable energy pricing from Independent Power Producers (IPPs) to PLN. MEMR Regulation 50/2017 and its revision under MEMR Regulation 4/2020 defined pricing based on BPP, setting prices higher or lower based on regional costs compared to the national average. However, using BPP as a benchmark for geothermal tariffs has significant drawbacks due to its heavy influence from the coal-dominated power sector, in particular for Java and Sumatra regions where the most geothermal potential sites are located. As of January 2023, coal-fired plants accounted for 66.01 percent of Indonesia's total capacity, distorting the BPP and affecting geothermal pricing. These factors suggest that the BPP model needs adjustments to incorporate external costs and provide a fairer comparison between coal and geothermal power, thus supporting more balanced and sustainable energy policies. Three key issues make BPP inappropriate for geothermal pricing:

1. Inequitable Incentives: Coal plants benefit from subsidies like the Domestic Market Obligation (DMO), keeping their costs artificially low. Without these subsidies, coal tariffs could be much higher and could fluctuate following its international price.
2. External Costs: BPP does not account for the environmental and health costs associated with coal power, such as emissions and pollutants, which have substantial social costs.
3. Supply Risks: Coal supply is unreliable, as seen in 2001 when PT Indonesia Power had to reduce its geothermal power plant operations due to coal shortages.

Geothermal Power Plant – electricity price

Capacity (MW)	Ceiling Price (HPT)							
	s.d 10 MW		>10 MW s.d. 50 MW		>50 MW s.d 100MW		>100 MW	
	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30
Staging Price (cent $/kWh)	9,76 x F	8,30	9,41 x F	8,00	8,64 x F	7,35	7,65 x F	6,50
Levelized Price (cent $/kWh)	9,25		8,92		8,19		7,25	

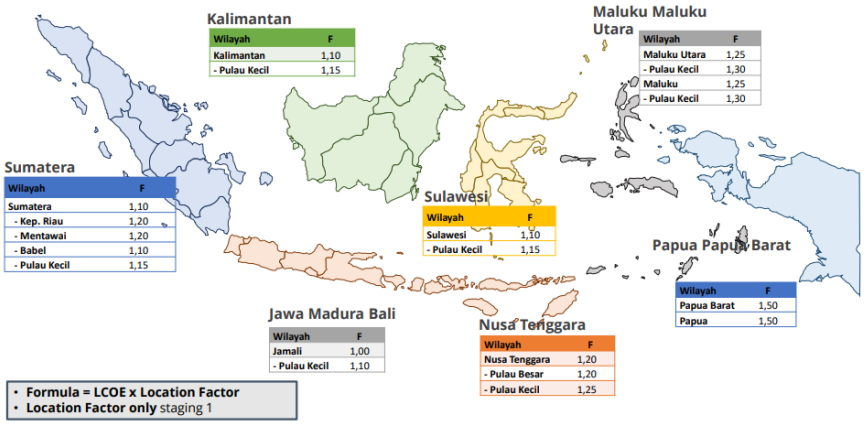

Figure 6: The base tariff and location factor of geothermal tariff under presidential regulation 112/2022.

Indonesia's geothermal tariff introduced a new ceiling with a staging tariff system in 2022, determined by the power plant's location and capacity. This method is specified in Presidential Regulation 112/2022, which updates the earlier ceiling tariff structure. The staging system splits the operational lifespan of a geothermal power plant into two phases: Stage 1 (years 1 to 10) and Stage 2 (years 11 and beyond). Each phase has a separate ceiling for the base tariff that developers can negotiate with PLN (GoI, 2022). Additionally, the location factor serves as a multiplier index for the base tariff during Stage 1. This adjustment accounts for the variation in development costs resulting from differing infrastructure conditions across regions (MEMR, 2022b). Figure 6 shows the distribution of base tariff and location factor. The calculation of the applied base tariff is below.

Tariff stage 1 =a greed tariff x location factor

Tariff stage 2 = agreed tariff

In recent discussions with stakeholders in the geothermal sector, several critical insights have been gathered regarding the new tariff scheme implemented for geothermal projects. Including:

1. Clarity on tariff for expansion of an existing project. A significant concern raised by stakeholders is the ambiguity surrounding tariffs for the expansion of existing geothermal projects. Currently, the regulatory framework does not clearly stipulate how tariffs are adjusted for additional units within existing projects. Developers argue that allowing expansion projects to secure the maximum tariff rate, akin to that of the first unit, would not only simplify financial planning but also maximize profitability. Stakeholders collectively suggest that a more effective regulatory approach would incentivize operational units immediately upon development, rather than deferring financial benefits until subsequent units are constructed. This immediate incentive could accelerate project expansion and contribute to more rapid scaling of geothermal capacity.
2. Staging Down Tariffs, the unique and complex nature of geothermal development, characterized by variable field conditions and decline rates, necessitates continual investment in make-up wells to maintain power output. However, the existing tariff staging poses a significant challenge. As stakeholders pointed out, the practice of reducing tariffs in later stages undermines project economics at critical phases when substantial investments are needed for maintenance and expansion. This reduction in tariffs can lead to diminished cash flows during periods that are crucial for the sustained operation and growth of the facility.

3.2.4 Fiscal Incentives

Indonesia's government has already launched several incentives for geothermal such as tax holiday/tax allowance, import tax exemption, and land tax exemption as shown in Figure 7. EBTKE (2022) emphasizes that the tax facility could reduce the levelized cost of electricity (LCOE) by 0.07-0.19 US cents/kWh. The explanation of each tax facility as below:

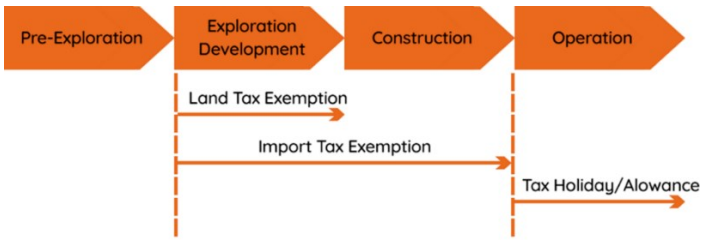

Figure 7: The effective period of Indonesia geothermal tax incentives per project period modified from EBTKE (2021).

The Government of Indonesia offers various fiscal incentives to promote investment and profitability in the geothermal industry. These incentives aim to create a favorable investment climate by reducing business costs and risks for investors. The incentives are provided through different government programs, encouraging businesses to invest in geothermal projects to maximize benefits (Chalk, 2001) (UNCTAD, 2000). Based on EBTKE (2022; 2021), Lesmana et al (2020), Winofa et al (2020), Abidin (2020), and Fadhillah (2023), current fiscal incentives implemented for the geothermal industry as shown in Table 3.

Table 3: Current fiscal incentives for geothermal.

Fiscal incentives	Remarks	Effective period of project stage
Tax holiday (PMK 130 / 2020)	The geothermal industry with an investment of more than IDR500 billion would be eligible to obtain 5 years tax holiday. The details of the tax holiday period as below: - 5 years for IDR500 billion to IDR1 trillion investments - 7 years for IDR1 to 5 trillion investments - 10 years for IDR5 to 15 trillion investments - 25 years for IDR15 to 30 trillion investments - 20 years for > IDR30 trillion investments the developer also would get a 50 percent reduction (for > IDR500 billion investments) for 2 years during the transition period after the facility. The geothermal developer with > IDR0.1 trillion investments is also eligible to obtain a 50 percent tax reduction in the first five years of operation, continued by two years transition period that obtains a 25 percent tax reduction (EBTKE, 2021)	Operation

Fiscal incentives	Remarks	Effective period of project stage
Tax allowance (GR 78/2019)		
- Investment Allowance	Reduction of taxable income equals 5 percent per year of the total investment for the 6-year period and 30 percent of the total investment for the full period. The investment should be owned by the main business entity and not transferred during the period (Abidin, et al., 2020; Lesmana, et al., 2020)	Operation
• Accelerated depreciation amortization	The Geothermal industry classified as "class 3" uses the double declining balance method with the 8-year period for tangible and intangible asset	Operation
• Loss carry over	The geothermal industry is eligible to perform loss carry forward for 5-year period with a maximum of no longer than 10 years. The geothermal as new and renewable energy is also eligible to obtain 1 year additional of the facility.	Operation
Land tax exemption (PMK 172/2019)	The land tax for the geothermal industry is exempted during the exploration phases (MoF, 2016). The land tax is charged during production phases with guidance from the directorate general of tax regulations No. PER-45/PJ/2013.	Exploration
Import tax and value-added tax exemption (PMK 172/2016)	The geothermal industry is 100 percent exempted from import tax for equipment that is not available / adequately produced in Indonesia (Abidin, et al., 2020; Lesmana, et al., 2020). The geothermal industry is not imposed VAT (Abidin, et al., 2020)	Exploration and development

As indicated by Kristina (2018) and Nugraha et al. (2017), the current tax incentives for geothermal projects in Indonesia have not demonstrated a significant impact in enhancing project attractiveness or reducing the cost of electricity generation. The incentives, as per IRENA (2022) and IESR (2022), include a tax holiday that allows for a 100 percent tax reduction for corporate income tax (PPh) for a period of 5 to 20 years. However, this incentive has not been effectively utilized, mainly because most renewable energy (RE) developers do not generate taxable profits during the initial five years of project implementation. Therefore, Fadhillah (2023) provide the case example of ineffective tax holiday period.

3.3 Technical

3.3.1 Resource

Indonesia is a region with the largest conventional convective geothermal resource potential in the world with 80 percent of the geothermal fields being spatially associated around volcanic areas. (ADB, 2018; Darma, et al., 2021). Geothermal fields in Indonesia are mostly situated within moderate to steep mountainous terrain. This geographical feature presents challenges in terms of accessibility and conducting geothermal survey activities in these areas (Hochstein & Sudarman, History of geothermal exploration in Indonesia from 1970 to 2000, 2008; Hochstein & Sudarman, Indonesian Volcanic Geothermal Systems, 2015). Steep terrain conditions present several challenges because they lead to extended times and higher infrastructure costs for drilling equipment mobilization, given that the roads are often uphill and winding. Moreover, finding flat and stable areas for constructing drilling well pads and power plants can be a challenge (Umam et al., 2018; Purba et al., 2020). The steep condition may also require many turns and greater lengths to reach target elevations for the pads. In such situations, many of the currently developed fields have resorted to directional drilling, which can increase costs and risks (Hole, 2006; Umam et al., 2018).

Based on the temperature classification by Sanyal (2005), it is confirmed that most of the developed geothermal fields in Indonesia fall in the high-temperature category. Making Indonesia have abundant lessons learnt to be applied for developing any potential high-temperature resource in the future.

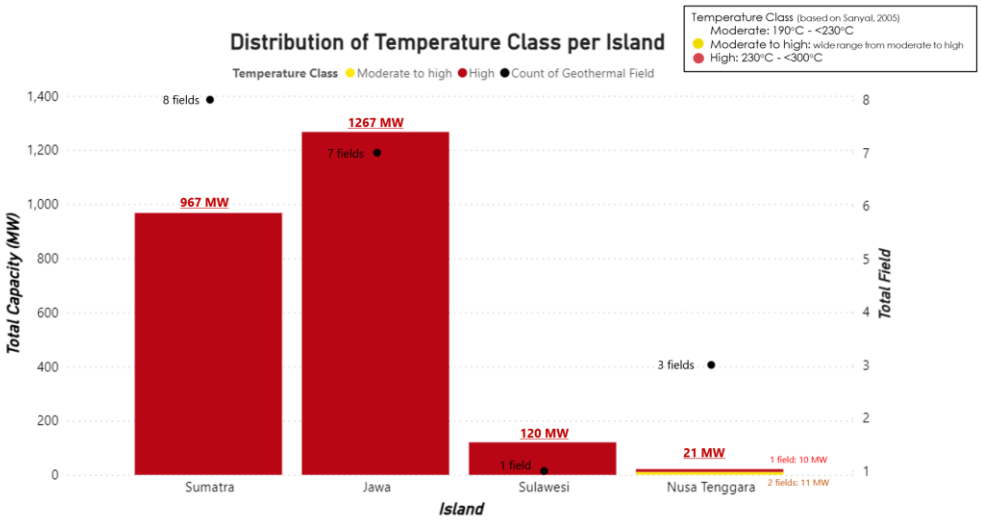

Figure 8: The distribution of resource temperature for geothermal projects in operation per island.

The Indonesian government has identified a list of fields requiring further analysis for potential future geothermal development. These prospects are outlined in the National Electricity Supply Business Plan (RUPTL) 2021-2030. The geothermal prospects in the future pipeline can be categorized into three rankings (Figure 9):

- Rank 1: National Strategic Project (PSN) which is already included in "Neraca Daya" of PLN RUPTL so they supposedly become the most prioritized project to develop.
- Rank 2: projects that are also already included in the PLN RUPTL, but no specific fields are assigned. The supply power is around 710 MW.
- Rank 3: potential projects that are not included in the PLN RUPTL and have no expected COD year. There are 106 projects with a total capacity of around 4.3 GW.

Based on their temperature, the fields listed in Rank 1 RUPTL 2021-2030 are predominantly categorized as high-temperature resources (13 of 22 fields). Most of them are in the exploration phase, such as Kepahiang, Rajabasa, Mount Sirung, while some fields have entered the development phase, including Ijen and Sungai Penuh. Additionally, some moderate-temperature systems are also included in Rank 1, such as Danau Ranau, Cisolok, Baturaden, with a targeted production of about 350 MW much lower than the targeted production from the high-temperature resource of about ~1,1 GW. Figure 9 shows the distribution Rank 1 project per area per temperature classification.

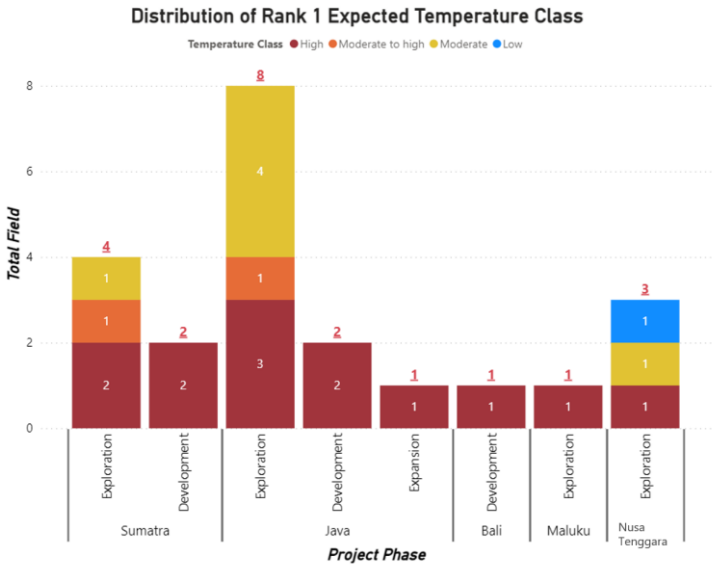

Figure 9: The rank 1 expected temperatures per area.

Slightly similar to the previous fields in Rank 1, several high-temperature fields are still included in Rank 3 (28 of 80 fields). However, a considerable amount of low to moderate-temperature geothermal fields have already been included on this list. It implies that after the fields listed in Rank 1 are already COD or developed (which are mostly high temperature), the fields listed in Rank 3 will become the next priority to be developed. Figure 10 shows the Rank 3 projects per area per temperature classification.

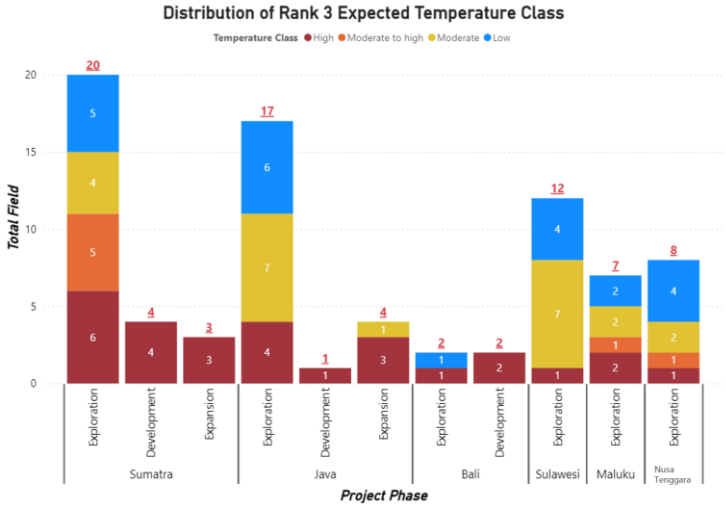

Figure 10: The rank 3 expected temperatures per area.

3.3.2 Power Plant Technology

Geothermal resources are utilized for electrical generation by extracting geothermal fluids from the reservoir and utilizing the resulting steam to drive a turbine connected to a generator (Ameri, et al., 2006). The following power plant technologies have been utilized in various Indonesia geothermal projects:

1. Single flash plants only use a single-pressure separator to separate vapor from the liquid. The separation occurs at constant pressure and temperature. The vapor generated is sent to a steam turbine, while the liquid is reinjected back to the ground (Assad, et al., 2017). This type of power plant is commonly employed in Indonesia, with utilization identified in 14 geothermal production fields, including Salak Awibengkok, Wayang Windu, Lahendong, Dieng, and Karaha Bodas (Siregar, 2004; Sulistyardi, 2010; Pambudi, Itoi, Jalilinasrabady, & Jaelani, 2014; Harvey & Wallace, 2016; Pambudi N. A., Geothermal power generation in Indonesia, a country within the ring of fire: Current status, future development and policy, 2018; Rachmat, Wibowo, & Surachman, 2018; Gunawan, 2021; Pratama, Widiatmo, & Ashat, 2021).
2. Multiple flash plants are a natural extension of the single-flash process. They employ two or three sequential separators, resulting in high, moderate, and low-pressure steam flows that drive the steam turbine. The use of the double-flash system has been explored in Muara Laboh (Oya & Takamiya, 2020).
3. *Dry-steam plants* are primarily used in vapor-dominated reservoir systems. In such reservoirs, most of the geothermal fluid has already reached the vapor phase due to conductive heat transfer from the surrounding water-saturated rocks (White, et al., 1971). In Indonesia, geothermal fields that employ these types of power plants include Patuha, Kamojang, and Darajat geothermal fields (Mendive et al., 2014; Setyawan et al., 2019).
4. *Binary power plant* is implemented for low-enthalpy geothermal systems. However, with advances in chemical technology, they can now operate at temperatures up to 200°C by using various secondary fluids (Redko A, et al., 2016). In addition, binary plants are occasionally employed in higher enthalpy fields that require additional pressure support, such as the Ngatamariki geothermal field in New Zealand (Assad, et al., 2017). Up until now, there is no solely binary power plant system installed for the power grid in Indonesia. A combined flash plant and binary plants have been utilized by Sarulla geothermal projects with a total 330 MW capacity. However, in the near future, a two-phase binary power plant will be commenced in Ijen field to fill an additional 31.4 MW capacity to the Java-Bali power grid.

Power plant units that are preferred to be used in Indonesia are predominantly single flash, comprising more than 50 percent of the total units in Indonesia, and supplying almost 50 percent of the total capacity (Figure 11). The dry steam plant, even though it is specifically used for vapor-dominated resources, is placed second in terms of used technology in Indonesia, showing a large development of vapor-dominated resources. It is followed by a combined cycle flash-binary plant and later a double flash plant. The single flash plant is predominantly used by fields developed before 2013, while from 2013 up to recent development, combined cycle flash-binary and double

flash started to commence. Combined cycle flash-binary, especially, is gaining popularity in recent development. As for the development trend, medium to large capacity development (51-100 MW) seems to be preferred. Developers, notably the JOC Sarulla Operation Ltd., tend to develop their resources on a large scale per unit (>100 MW) using combined cycle flash-binary.

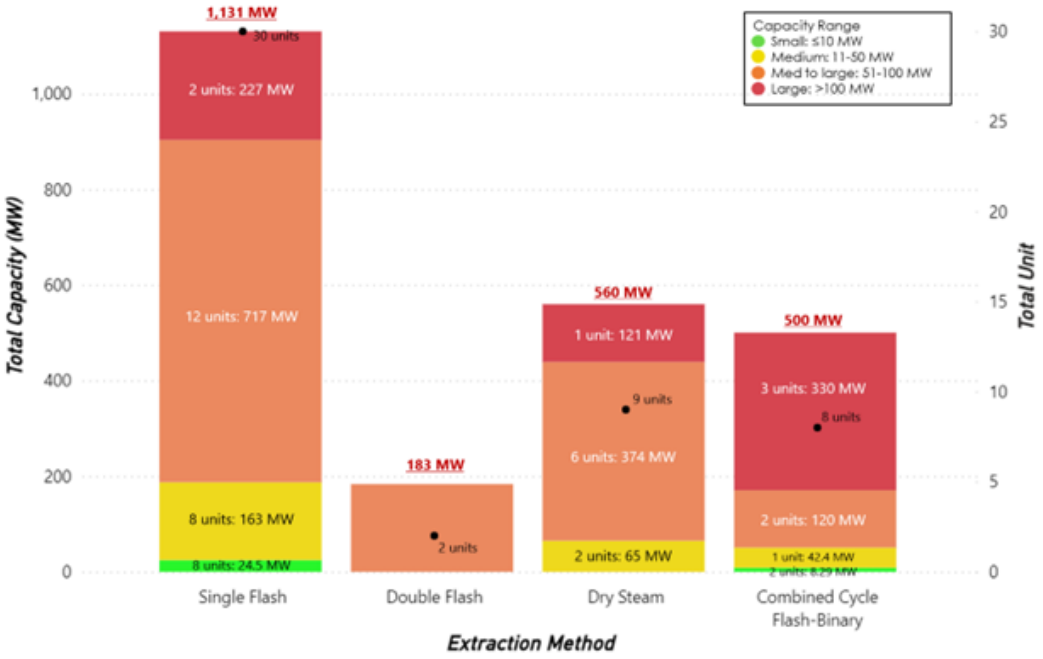

Figure 11: The installed capacity of power plant technology in Indonesia.

3.4 Social-Environmental

Geothermal energy is considered as sustainable and clean for the community (Cataldi, 1999). However, several geothermal projects faced social rejections due to a lack of public understanding of geothermal projects, lack of instant benefit to the community, and disturbance to the landscape. The significant scale rejection becomes a major issue that leads to the delay and cancellation of the geothermal projects (i.g Mt Lawu, Tampomas, Tangkuban Parahu). Social conflict could negatively impact projects/corporate reputation and financial perspective since the social rejection could lead to project delay and nonproductive time (Fadhillah, et al., 2022).

Fadhillah (2022) emphasizes that environmental issues as the most significant aspect of the geothermal projects involved almost in all the rejections (Figure 12). The environmental concerns are water sources such as scarcity and contamination, soil fertility, natural disasters (floods, landslides, and earthquakes), and accidents during drilling and well testing. The economic concerns related to the community anti-trust with land acquisition mechanisms, disruption to mass agricultural areas, and natural tourist attractions as a local occupation. Furthermore, cultural issues are related to the concern that project activity would disturb historical-sacred places, traditional houses, and communities.

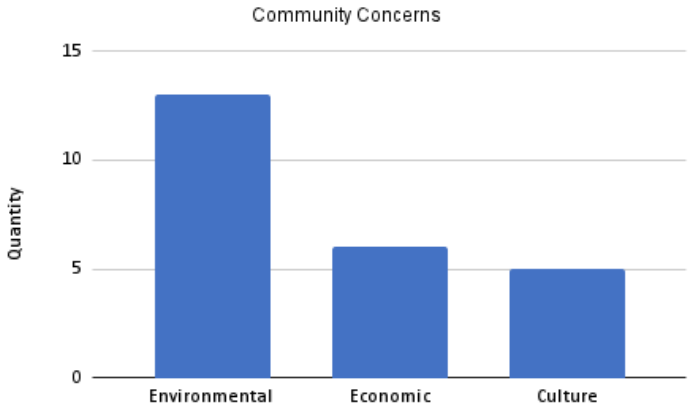

Figure 12: Community concerns to geothermal projects where each rejection may derive from more than one concern.

4. FUTURE OF INDONESIA GEOTHERMAL: SHIFTING RESOURCE PARADIGM

Indonesia's geothermal landscape is undergoing a significant transition with an increasing focus on low to moderate-temperature geothermal systems. Traditionally, high-temperature systems have dominated the exploration efforts; however, recent developments indicate a promising potential in low-enthalpy systems that have yet to be fully tapped. Despite the inclusion of numerous such fields—like Gunung Endut, Tampomas, Sembalun, and Galunggung—in Indonesia's Geothermal Development Pipeline as per the Electricity Supply Business Plan (Rencana Usaha Penyediaan Tenaga Listrik 2021-2030), no low-temperature fields have been developed so far (Putriyana L., Daud, Saha, & Nasruddin, 2022). The challenges in developing low to moderate-temperature in Indonesia, including:

1. **This shift necessitates a deeper understanding of appropriate exploration and production methods** tailored to the unique characteristics of these lower-temperature resources. One of the primary challenges is the limited experience and historical data regarding the successful exploitation of low to moderate-temperature geothermal systems. Unlike high-temperature systems, which have been extensively developed and studied, these lower-temperature fields lack documented methodologies and success stories that can guide developers and reduce perceived risks. Some development strategies and technologies are applied for several low-temperature geothermal fields worldwide, such as Brady in the USA and Flúdir-Midfell in Iceland. Although their condition (e.g., geologic setting, geothermal characteristic) is very different from in Indonesia, however, studying development strategies and technologies implemented in low-temperature geothermal fields worldwide could serve as a first step to initiate particularly low geothermal prospects development in Indonesia.
2. **Technology innovation and adaptation**, the need for specialized technology and approaches tailored to effectively explore and exploit these systems adds another layer of complexity. The current geothermal technology, flash system, is predominantly designed for higher temperature resources, necessitating adaptation of new technology, binary power plant, to produce the resource effectively.
3. **De-risking method and investment incentives**, the gap in expertise not only elevates the risk associated with these projects but also influences the expected returns as higher risk requires higher return, potentially deterring investment attractiveness. To address these challenges, the role of de-risking facilities becomes crucial. There is a critical need for the government to enhance current de-risking measures to better share and mitigate project risks associated with these geothermal prospects.

Additionally, the Indonesian government is urged to adapt and evolve its regulatory frameworks to support more innovative approaches to revenue streams. These could include off-grid/captive use mechanisms, power wheeling arrangements, and direct utilization of derivative products like green hydrogen and minerals extraction. Such regulatory adaptations would not only foster the development of low to moderate-temperature geothermal resources but also align with global trends toward more sustainable and versatile energy solutions. By doing so, Indonesia can secure its position as a leader in geothermal energy while promoting sustainable development within the sector.

5. CONCLUSION

In conclusion, Indonesia's geothermal resources offer vast potential, yet the exploration and development processes still face significant challenges that must be addressed to optimize utilization. While the government has established a robust regulatory framework and provided fiscal incentives to spur investment, these measures require enhancement to fully capitalize on the evolving geothermal resource conditions. As Indonesia transitions from high to lower-temperature geothermal systems, there is a pressing need for adaptation in technology and strategies. The shift towards binary technology to accommodate moderate temperature resources necessitates a strategic response to mitigate the risks associated with the learning curve and inexperience in this area. Strengthening exploration de-risking programs and refining development strategies are critical steps towards fostering a conducive investment environment and achieving Indonesia's ambitions for green electricity generation. This paper underscores the importance of an integrated approach that encompasses technological adaptation, regulatory support, and financial incentives to drive the future of geothermal energy in Indonesia.

Keywords: Indonesia Energy Transition, Geothermal Energy, Renewable Energy Potential, Solar and Wind Power, Net-Zero Emissions 2060

ABSTRACT

As Indonesia navigates its ambitious journey towards net-zero emissions by 2060, understanding the role and potential of renewable energy sources becomes imperative. This study presents a rigorous comparative analysis of geothermal, solar, and wind energies, emphasizing their capacity, environmental impact, economic benefits, and feasibility for scale-up within the Indonesian archipelago.

This study findings reveal that Indonesia possesses substantial untapped geothermal potential, with key sites located along the Pacific Ring of Fire. Geothermal energy, capable of providing stable baseload power, is identified as the most viable option for immediate scale-up due to its consistent energy output and lower environmental footprint compared to solar and wind. While solar and wind energy offer significant potential, their intermittent nature and higher land use requirements necessitate robust energy storage solutions and strategic siting to minimize ecological impacts. Indonesia's geothermal resources, estimated at 23,060 MW, are primarily concentrated in Sumatra and Java, offering a stable baseload power with over 16,676.94 GWh produced annually. In contrast, solar and wind energies, despite having a combined potential exceeding 3,400 GW, currently deliver less than 1,000 GWh per year. This underutilization underscores significant scalability opportunities, especially for geothermal energy, which currently operates at only 10.48% of its potential.

The economic analysis reveals that geothermal energy not only supports substantial direct and indirect employment but also contributes robustly to government revenues through fixed and production-based contributions, significantly more than solar and wind. Geothermally enhanced areas witness substantial infrastructural and community development, catalyzing local economic growth.

1. INTRODUCTION

Indonesia has large potential for untapped renewable energy sources, including geothermal, wind, hydro, bio, and solar. Renewable energy provides local and reliable energy supply that increases demand in the future. Indonesia has a rigid plan to accelerate renewable energy utilization the primary source to support energy growth and achieve the country's net zero carbon emissions target (IRENA, 2022). Figure 1 shows Indonesia’s energy demand projection from 2021 to 2032 based on the Ministry of Energy and Mineral Resources-MEMR (2021). The business-as-usual (BaU) scenario shows 4.8% growth per year, while the optimistic (OPT) scenario shows 6% growth yearly. The graph emphasizes electricity as the most significant growing energy demand in ten years.

The significant increase in electricity demand is aligned with the projected power plant supply from 2021-2032 based on MEMR (2022) as shown in Figure 2. The power supply from renewable energy will support 21%-28% of electric power generation in 2032. It has the most increasing pattern over the year, with a detailed breakdown in Figure 3. It is aligned with regulated national energy mix that emphasizes enhancing renewable energy utilization to replace fossil energy. The Government of Indonesia (GoI) set the renewable energy contribution to 23% of the energy mix in 2025, increasing to 31% in 2030.

The more detailed percentages of renewable electricity energy are shown in Figure 3 Indonesia energy mix for power generation in 2021-2030 (modified from PLN, 2021). It emphasizes geothermal as the second largest power generation from renewable energy by 2025. It targeted to support 16.9% of renewable energy power generation, equal to 7.56% of the total national electricity demand, with the increasing pattern over the year (PLN, 2021). Geothermal is also expected to be baseload of electricity that replaces coal’s primary power generation in Indonesia (World bank, 2011).

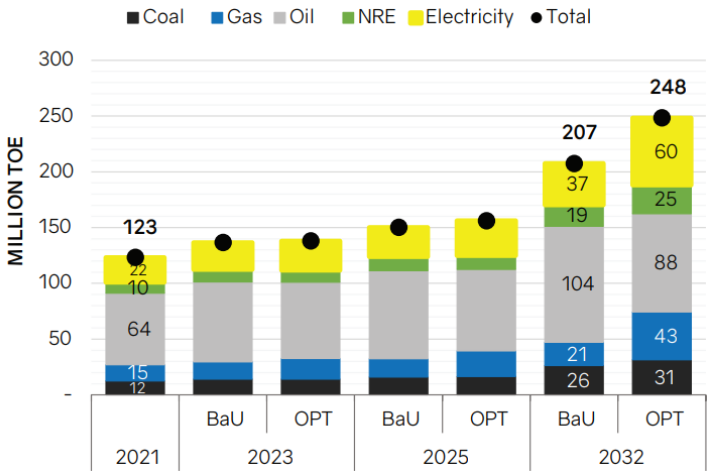

Figure 1: Indonesia energy demand projection 2022-2032 (MEMR, 2022).

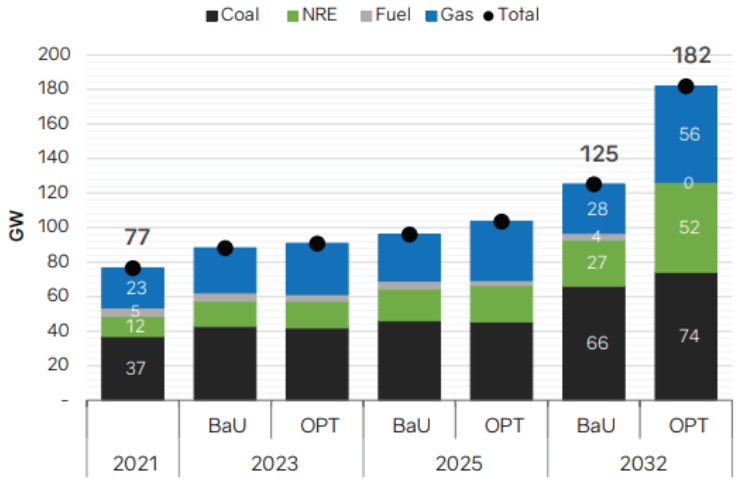

Figure 2: The power plant capacity projection for 2021 – 2032 (DEN, 2022).

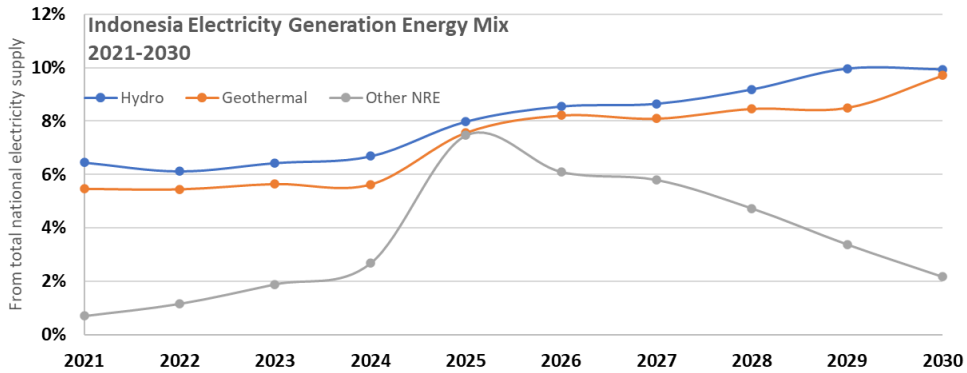

Figure 3: Indonesia energy mix for power generation in 2021-2030 (modified from PLN, 2021).

The primary objective of this study is to conduct a comprehensive comparative analysis of geothermal, solar, and wind energy sources in Indonesia, evaluating their capacity, environmental impacts, economic benefits, and scalability. This analysis aims to identify the most viable renewable energy source for immediate scale-up within the Indonesian archipelago to aid in achieving the nation's ambitious net-zero emissions target by 2060. The central research question of this study is: What are the comparative of geothermal, solar, and wind energy in contributing to Indonesia's renewable energy landscape?

2. INDONESIA GEOTHERMAL LANDSCAPE

The geothermal development in Indonesia has started from colonized era with commercial utilization remarked through Kamojang Geothermal Power Plant (30MW) in 1983. Nowadays, Indonesia is top two geothermal country

in the world with 2,417 MW installed capacity from approximately 23 GW total potential. It means that Indonesia only utilized around 10% of total potential with average additional capacity around 60 MW per annum. Government of Indonesia has plan to utilize geothermal as baseload to replace coal power plant and set the target of utilization to reach 5,799 MW in 2030. The government target emphasizes the significant increase in average of additional installed capacity toward 488 MW per annum from 2024 to 2030. This bold target needs to be achieved by catalyzing geothermal development though better investment condition. Figure 4 shows the historical and target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

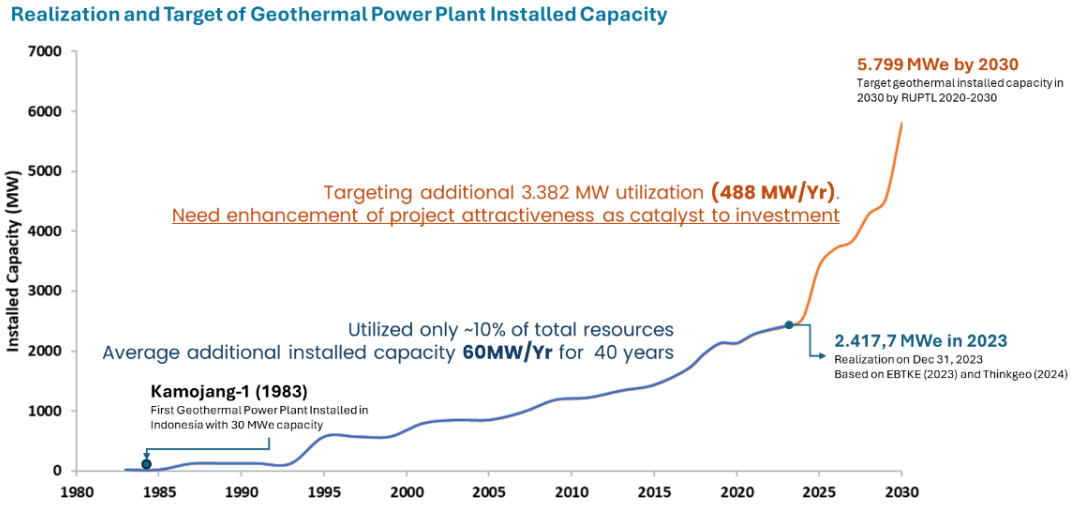

Figure 4: Indonesia geothermal power plant installed capacity and target for 2023 based on EBTKE (2023) and Thinkgeo (2024)

There are 46 geothermal power plants, including the expansion unit, developed by State-Owned Enterprises (SOE) and Independent Power Producer (IPP) in 17 geothermal working areas with dominantly located in Sumatera and Java. From existing conditions as shown in Figure 5, the top-3 of geothermal producers in Indonesia is dominated from IPP sector with KKOB Star Energy Geothermal Ltd. owns the highest capacity among other developers (Figure 5) with the total of 874 MW coming from only 3 geothermal fields. Meanwhile, PT Pertamina Geothermal Energy (Persero) is in second place with the total of 677 MW coming from 6 geothermal fields. These two developers owning half of the total installed capacity in Indonesia while the remaining half is supplied from KKOB Sarulla Operation Ltd., PT Supreme Energy, KS Orka Renewables, PT Geo Dipa Energi (Persero), and PT PLN (Persero). These two majority developers seem have a different development strategy. KKOB Star Energy Geothermal Ltd. tends to maximize the development of a few fields while PT Pertamina Geothermal Energy (Persero) owns more fields with lesser capacity supply.

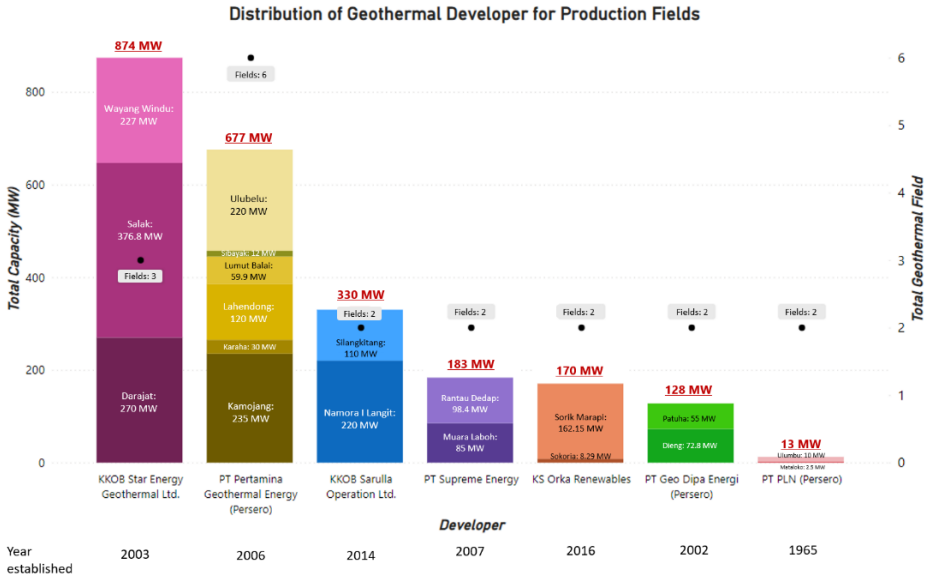

Figure 5: Geothermal player in Indonesia.

3. INDONESIA RENEWABLE ENERGY OVERVIEW

3.1 Geothermal

Geothermal power is energy derived from the natural heat of the earth, captured from hot springs, geysers, volcanic activity, or other processes occurring beneath the Earth's surface. This heat is used to produce steam that drives turbines to generate electricity. Indonesia, with its position along the Pacific 'Ring of Fire', has access to numerous geothermal sites where the Earth's crust is thin and volcanic activity is high, facilitating easier access to geothermal energy.

Geothermal energy is harnessed by extracting natural heat, typically in the form of steam or hot water, from reservoirs via production wells. This steam is then directed to turbines, where its mechanical energy is converted into electricity. The remaining fluid is reinjected back into the subsurface. The mechanism is illustrated in Figure 6. Consequently, geothermal energy utilization is limited to its locations due to its site-specific nature. Additionally, geothermal plants necessitate ongoing monitoring and maintenance to address scaling and corrosion issues in equipment. Geothermal energy, with its high energy density, can generate more power from a smaller footprint compared to solar or wind energy sources. This characteristic makes it a compelling option for renewable energy production, particularly in regions where land availability is limited.

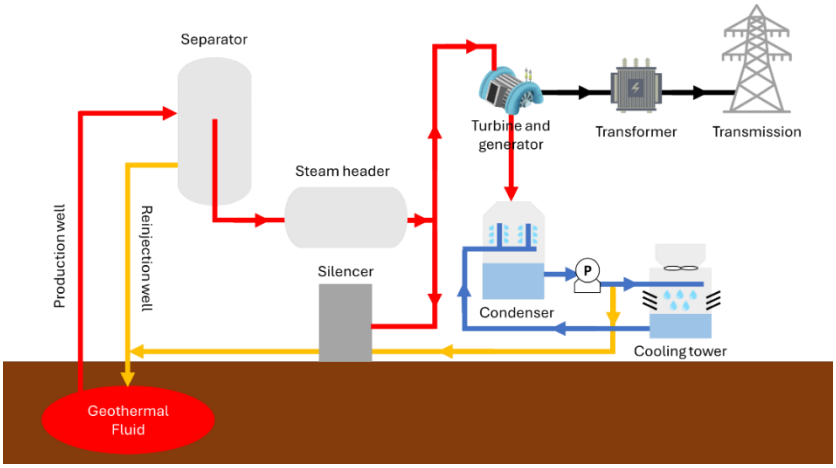

Figure 6: Schematic illustration of geothermal power generation mechanism. Modified design from Yokogawa (2024).

Geothermal technology, well-established and continually innovating, focuses on improving efficiency and reducing costs, particularly for low-medium enthalpy systems (EBTKE, 2023b). Ongoing research aims to enhance resource exploration, optimize drilling techniques, and develop enhanced geothermal systems (EGS) technologies to expand accessible resources. With stable and reliable power generation, unaffected by weather conditions or time of day, geothermal energy can serve as baseload power, typically without the need for storage due to its constant output (Dipayana & Ramadhan, 2022a; IESR, 2022a). In periods of reduced availability, hybrid systems with biomass or conventional backup can maintain supply, with minimal integration challenges compared to intermittent renewables (IESR, 2022a).

Geothermal is currently used widely as an energy source. In Indonesia, the utilization of geothermal energy contributes to government revenues through various tax and non-tax streams. Tax streams including Income Tax (PPh), Value Added Tax (VAT or PPN), Land and Building Tax (PBB), Import Duties, Taxes in the Framework of Import (PDRI), and local taxes and regional levies contribute significantly to state coffers (EBTKE, 2023b). Conversely, the non-tax revenues (PNBP) are sourced from state levies, with 20% allocated to the Central Government and 80% to the Regional Government. These levies consist of fixed contributions for exploration and exploitation, set at $2 and $4 per hectare per year, respectively, alongside production contributions calculated at 5% of the selling price for steam and 2.5% for electricity. Furthermore, production bonuses, following the same 20:80 distribution between the Central and Regional Governments, are also part of the revenue generation scheme (EBTKE, 2023b).

Indonesia ranks among the world's leading geothermal energy producers, securing second place after the USA in terms of generated power capacity, contributing to 14% of the total world installed capacity (ThinkGeoEnergy, 2024). With a current installed capacity of 2.4 GW as of 2024, the nation is actively tapping into its estimated 23 GW potential. Despite this progress, approximately 90% of the total geothermal potential remains untapped, including low-medium temperature resources, indicating ample room for further exploration and development. Geothermal projects are widespread across the archipelago, with significant operations concentrated on Java and

Sumatra, complemented by emerging ventures in less developed regions like Sulawesi and East Nusa Tenggara. Nonetheless, a substantial portion of Indonesia's geothermal potential remains unexplored, underscoring significant opportunities for future expansion. This potential growth is further highlighted in the targets outlined in the RUPTL 2021-2030 (PLN, 2021a; EBTKE, 2023b), aiming for significant additional capacity by 2030.

The Indonesian government, alongside companies like PT Pertamina Geothermal Energy (Persero), is keen on expanding geothermal capacity. This effort is in alignment with the country's $20 billion Just Energy Transition Partnership (JETP) aimed at accelerating the adoption of renewable energy sources and reducing reliance on fossil fuels. In accordance with this effort, the Fast Track Program for geothermal projects also exists to expedite project development. Such initiatives underscore Indonesia's commitment to sustainable energy development and position the country as a key player in the global transition towards cleaner and more sustainable energy sources.

Despite Indonesia's significant progress in harnessing geothermal energy, several challenges persist that hinder further expansion of this renewable resource, notably the high initial cost investment required for geothermal development. Geothermal exploration and development involve substantial upfront investment and geological risk, impacting project finance and insurance rates. Moreover, the development phase of geothermal projects demands expensive capital and entails high upfront investment, ranging from 4.5 to 9 million USD/MW (GRG-Geoenergis, 2024). These costs are offset by moderate to low operational costs and a high-capacity factor over time. The levelized cost of electricity (LCOE) for geothermal energy in Indonesia ranges from 3.56 to 12.06 cUSD/kWh, with capital expenditures (CAPEX) accounting for 6.65 cUSD/kWh and operational expenditures (OPEX) comprising 0.74 cUSD/kWh according to the latest updates by IESR (2024a; 2024b). Additionally, the high-risk, high-cost nature of investment in the exploration stage of geothermal projects poses a significant challenge. Exploratory drilling and reservoir assessments entail substantial financial commitments and technical uncertainties, making it a daunting prospect for investors. Moreover, the development phase of geothermal projects also demands expensive capital and entails high upfront investment notably in the SAGS and power plant construction, contributing to the overall risk profile of such ventures (ESMAP, 2012). Furthermore, geothermal projects often have long development times due to the exploration and drilling phase, typically spanning 5-10 years from exploration to operation (EBTKE, 2023b). Despite these challenges, integrating geothermal energy with other renewables and storage can optimize the energy mix and enhance grid stability despite the high initial costs with addition of stable output of energy so it is not reliant on storage.

Several initiatives have been implemented in Indonesia to promote geothermal energy through de-risking schemes, particularly in the exploration stage. Risk mitigation strategies, including government incentives and international funding, are employed to attract investment in the geothermal sector (World Bank, 2021). One notable initiative is government drilling performed by the Geological Agency to gather essential subsurface information and reduce exploration risks for potential developers. Additionally, Indonesia's geothermal sector has attracted international investment, supported by government policies and international funding (ADB, 2020). Investment rates are influenced by resource risk and high upfront costs, but initiatives like the Geothermal Exploration Risk Mitigation Program (GEUDP) and Geothermal Resource Risk Mitigation (GREM) aim to mitigate these financial risks associated with geothermal exploration activities by providing funding support for exploration drilling.

3.2 Wind

Wind power harnesses the kinetic energy from the wind to turn blades connected to an electric generator to produce electricity. The rotor blade in the wind turbines will rotate when the wind blows following the wind direction for efficiency, and drives a generator inside the turbine housing (Figure 7). The rotational energy is then converted into electrical energy and transmitted to the grid. Optimal performance would be achieved by regular maintenance of the wind turbines, especially for offshore installations.

Modern wind turbines are installed on land or offshore and come in various sizes to serve different needs, from small turbines for individual homes to large wind farms that contribute to the grid. Offshore wind projects offer substantial scalability but at higher costs (GWEC, 2021; GWEC, 2022) while onshore projects are limited by site suitability and land availability.

The wind energy technology is considered mature already with current improvements focused in turbine technology and efficiency. As technology matures and costs decrease, wind energy promises long-term price stability, particularly in regions with strong and consistent wind resources (Wiser, et al., 2011; US DOE, 2021; IEA, 2023), such as coastal regions or open plains. Advances in turbine technology, including larger rotor diameters for lower wind speed sites and floating offshore wind turbines, are expanding feasible locations.

The wind energy in general is intermittent with variable energy density which is highly dependent on local wind conditions. As it is influenced by the weather, location, and altitude, wind energy is considered cannot be a baseload supplier. To manage short-term intermittency, wind energy often utilizes battery storage and it also

necessitates advanced grid management and hybrid systems with other energy sources to maintain grid stability (IESR, 2022a; IRENA, 2022a).

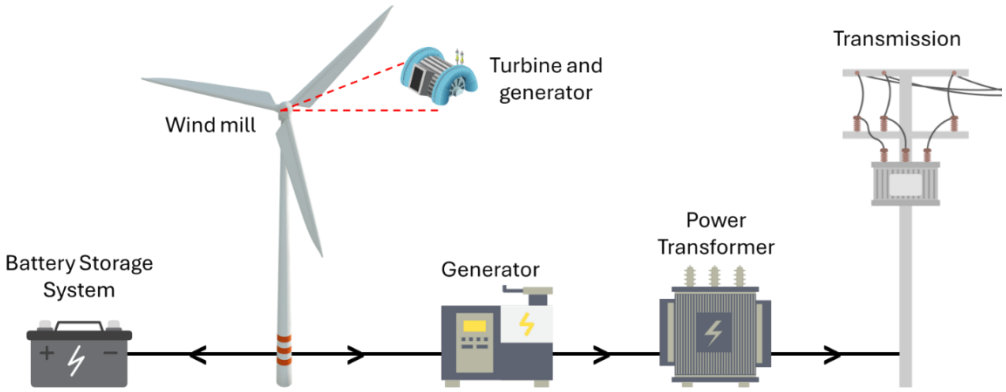

Figure 7: Wind energy power generation from the turbine to the grid and storage.

Wind energy in Indonesia is in a nascent stage. With its long coastline and hilly terrain, Indonesia has pockets of high wind potential, especially in the East and in coastal areas facing the open sea such as East Nusa Tenggara, South Kalimantan, West Java, South Sulawesi, Aceh, and Papua where the wind velocity could reach more than 6 m/s. There have been several pilot projects and studies to evaluate the feasibility of wind farms in the country. As technology advances and investment increases, wind power has the potential to become a more significant part of Indonesia's renewable energy mix, complementing the existing geothermal and solar resources.

Indonesia's wind energy potential is estimated at 155 GW coming from offshore potential for 94.231 GW and onshore for 60.647 GW. The current installation is only 154.3 MW, indicating the underutilization of substantial untapped resources (AEAI, 2022; MEMR, 2022; EBTKE, 2023b; BAPPENAS, 2024). A strategic partnership that aims to develop this sector further, reflecting a growing interest in wind energy despite its current early development stage. Areas like Nusa Tenggara Timur showcase the highest wind energy potential, with the government providing supportive policies and incentives for growth.

The levelized cost of electricity (LCOE) for Onshore Wind in Indonesia ranging from 3.92 to 18.77 cUSD/kWh. According to the latest updates by IESR, the refined LCOE stands at 7.47 cUSD/kWh, with capital expenditures (CAPEX) accounting for 5.45 cUSD/kWh and operational expenditures (OPEX) comprising 2.01 cUSD/kWh (IESR, 2024a; IESR, 2024b). The wind energy project has a moderate development time, ranging from about 3-5 years from site selection to operation but it is subject to permitting and construction timelines.

The development cost for wind project is influenced by site-specific factors and the cost of turbines. The development will be more cost-effective when developed at suitable sites. The onshore wind is among the lowest-cost sources of new electricity generation (Lazard, 2023). The relatively higher cost is usually due to the nascent stage of wind energy development in the country as a result of high initial investments and complex logistics. Offshore wind, not yet developed in Indonesia, would entail higher costs than onshore wind due to the complexities of working in marine environment (GWEC, 2020).

The wind power sector contributes to governmental financial inflows via a dual revenue framework encompassing taxes and non-tax avenues. Taxation revenue from wind power includes Income Tax (PPh), Value Added Tax (VAT/PPN), Land and Building Tax (PBB), Import Duties, and PDRI taxes, in addition to local taxes and regional levies. On the non-tax front (PNBP), the government collects land lease fees and various licensing fees, such as those for business and environmental licenses. Moreover, wind power projects may incur royalty fees when utilizing state-owned resources, further enhancing the sector's fiscal contribution.

Similar to solar, wind projects increasingly incorporate storage to mitigate intermittency. Large-scale batteries and hybrid systems offer long-term solutions but require significant investment. The financial viability of the development improves with advancing storage technologies, decreasing costs, supportive policies, and increasing market competitiveness resulting in significant growth globally in the industry (GWEC, 2021; IRENA, 2021a). Additionally, wind energy, particularly onshore, has seen significant cost reductions, making it competitive with traditional and other renewable energy sources. Robust investment is also seen in offshore wind, facilitated by financial instruments like green bonds and power purchase agreements (GWEC, 2021; GWEC, 2023).

3.3 Solar

Solar power technology captures energy from the sun and converts it into electricity through photovoltaic (PV) cells. These cells allow photons to knock electrons free from atoms, generating electricity directed to the grid or

stored in batteries. The overall mechanism is illustrated in Figure 8. Solar installations range from small rooftop setups to large utility-scale farms, offering scalability. The solar power technology is already mature with ongoing advancements in efficiency and cost reduction. Recent innovations include using higher efficiency PV materials, building-integrated photovoltaics (BIPV), usage of emerging technologies like perovskite solar cells, and floating solar panels on reservoirs and lakes (IRENA, 2019; NREL, 2021; Sharma, 2023). The modular nature of solar technology facilitates rapid deployment (IESR, 2019; IESR, 2021a).

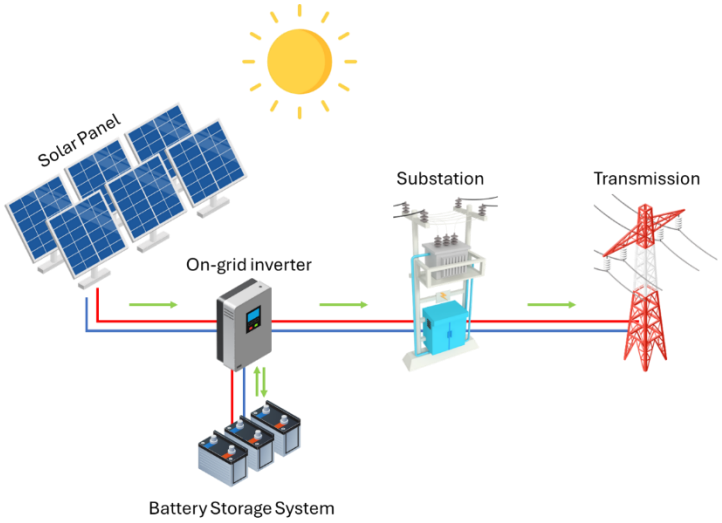

Figure 8: Illustration of solar power generation flow from radiation capture to electricity grid and storage. Modified design from Avenston (2024).

Solar panels require minimal maintenance, primarily cleaning to maintain efficiency. However, solar provides low energy density and requires expansive areas to generate significant power output. Additionally, the intermittent nature of solar energy necessitates the implementation of energy storage solutions to ensure reliability, often complemented by battery systems to enhance flexibility in power distribution. In addressing the storage challenge, solutions such as pumped hydro and flow batteries are commonly employed for larger-scale storage. Furthermore, the integration of solar power with other renewable energy sources and advanced grid management technologies is crucial to bolster reliability and optimize energy production. However, achieving consistent reliability is contingent upon overcoming daily and seasonal variations influenced by factors like weather conditions, geographic location, temperature fluctuations, and daylight duration (IESR, 2022a; IRENA, 2022a). Despite these complexities, solar energy remains a sustainable and progressively cost-effective solution for power generation, playing a pivotal role in meeting global energy demands while mitigating environmental impacts.

The solar energy usage is virtually unlimited and applicable worldwide with particularly strong growth in regions with high solar irradiance. The solar energy potential is widely accessible in Indonesia, scalable for residential to industrial utility scale. The abundant sunshine across the tropical region offers a theoretical potential of over 200 GW peak. Rural electrification programs have been particularly successful in using solar power, and there is a growing trend in urban areas to adopt solar energy for residential and commercial use. Indonesia has a solar potential of 3,294 GW, yet only 317 MW of capacity is currently utilized. Solar resources are abundant across the nation, especially in regions like Nusa Tenggara Timur (NTT), West Kalimantan, and Riau where they experience higher levels of radiation. Indonesia's solar energy sector is burgeoning, with the government actively promoting solar panel installations through incentives and programs. The Indonesia Solar Energy Outlook 2023 underscores solar PV's role in the energy transition, highlighting ongoing projects and future plans. With an average generation potential of 4.8-5.1 kWh/m^2/day, solar energy presents a low-cost and flexible option, supported by investments and initiatives like those from East Ventures into companies such as Xurya, which focuses on expanding rooftop solar power plants. However, compared to its potential, solar power remains underutilized in Indonesia, with opportunities for expansion particularly in decentralized (notably eastern regions) and off-grid areas (PLN, 2021a; PLN, 2021b).

Solar projects typically entail lower upfront costs and shorter development timelines, mitigating investment risk, although policy and regulatory uncertainties can introduce additional challenges (IESR, 2021b; IRENA, 2023a). Development timelines are relatively short, ranging from 1 to 2 years for utility-scale projects and even shorter for residential and commercial installations. Solar energy requires significant investment in storage to manage intermittency (IESR, 2022a). The cost-effectiveness of solar investments depends on the scale of storage and advancements in battery technology (IRENA, 2022b).

Currently, the global photovoltaic (PV) price is declining and battery costs are decreasing, enhancing the feasibility of solar technology (IESR, 2022a; IRENA, 2022b; IRENA & ACE, 2022). It fueled the expansion of the technology although challenges persist in distribution and installation (IRENA & ACE, 2022). Supportive policies such as government incentives also have made solar investments more attractive (IESR, 2022a; BNEF, 2023). Innovative financing models like solar leasing and power purchase agreements (PPAs) have broadened access to capital (SEIA, 2024). In the global case, this results in rapid growth of solar energy market, attracting both local and international investment propelled by cost reductions and efficiency improvements.

The levelized cost of electricity (LCOE) for solar PV utility scale in Indonesia ranges from 4.09 to 10.09 cUSD/kWh, with a refined LCOE of 5.79 cUSD/kWh (4.92 cUSD/kWh for CAPEX and 0.87 cUSD/kWh for OPEX), as per the latest updates by IESR (2024a; 2024b). There has been a 78% decline in solar PPA prices from 2015 to 2022. The current interests in Indonesia's renewable energy industry also emphasize the potential of utility-scale and floating solar power plants. Clear auction mechanisms, transparent local content requirements, and stable policies are advocated to foster the solar industry's growth and meet Indonesia's solar targets (IESR, 2022b).

Utilizing solar energy in Indonesia presents an opportunity for revenue generation through various channels. Within the solar energy sector, the government can generate revenue through both taxation and non-tax mechanisms. Tax revenues are sourced from Income Tax (PPh), Value Added Tax (VAT/PPN), Land and Building Tax (PBB), Import Duties, Taxes related to Imports (PDRI), and a variety of local taxes and levies. Additionally, non-tax revenues (PNBP) can be derived from land lease fees, licensing fees such as business and environmental licenses, and potentially royalties, particularly in cases where solar power projects utilize state-owned resources. These revenue streams contribute to the financial sustainability of solar energy initiatives while supporting government budgets and public services.

3.4 Comparison of geothermal, wind, and solar

Indonesia stands at the forefront of renewable energy, boasting a landscape rich in geothermal, solar, and wind resources. These abundant sources each contribute significantly to the nation's energy transition, showcasing Indonesia's commitment to sustainable development and environmental stewardship. Geothermal energy serves as a cornerstone due to its vast and stable output. Geothermal energy, deriving from subsurface reservoirs primarily found in volcanic areas, offers stable output but requires high initial investment costs. Despite high initial costs, geothermal's consistent base-load capacity offers a predictable financial model.

Conversely, solar and wind are rapidly emerging as key components for the country’s energy transition, supported by technological advancements and favorable government policies. Open-spaced areas provide ideal conditions for the expansive development of these renewable sources. Both solar and wind energy rely on surface factors such as weather and climate and offer lower initial costs, albeit with challenges related to energy storage and grid integration. Managing the intermittency of solar and wind power is crucial for their financial viability, necessitating the implementation of energy storage systems and improved grid integration. However, advancements in technology and changing market dynamics, including decreasing costs for energy storage, hold promise for enhancing the competitiveness of these renewable sources.

The load curve of a power system represents the variation in demand for electricity over time, typically across a 24-hour period. The provided illustration delineates how different fuel sources contribute to meeting this demand (Figure 9), focusing on renewable sources such as geothermal, solar, and wind energy. Geothermal energy, characterized by its ability to provide a constant output, forms the base layer of the load curve, indicating its role as a reliable and stable energy source. Above it, solar and wind energies fluctuate, filling in the mid to peak demand spaces, mirroring their variable nature and dependency on environmental factors.

The capacity factor is a critical measure of the efficiency of power plants, reflecting the actual output over a period relative to the maximum possible output under continuous operation. Geothermal power plants typically have high capacity factors due to the consistency of heat supply from the earth’s core, making them highly reliable for base-load power generation. In contrast, solar and wind energies exhibit lower capacity factors, as they are subject to the variability of weather and time of day. The Figure 9 demonstrates the varying capacity factors of energy sources, with geothermal energy maintaining a steady presence, while solar and wind peak during certain periods.

The load curve and capacity factor analysis underscore the complementary roles of geothermal, solar, and wind energy in an integrated power generation system. Geothermal energy's consistent output is crucial for meeting the continuous baseline demand. It is less affected by climate variability, offering a stable and reliable energy source under changing climate conditions (IPCC, 2023a; IPCC, 2023b). Solar energy's effectiveness can be impacted by changes in weather patterns, cloud cover, and temperature (IPCC, 2011). It peaks during daylight hours, providing substantial energy during midday peaks. Similar to solar energy, wind energy is also affected by weather changes. A shift in the wind pattern may occur due to climate change, affecting wind farm efficiency (Kara & Sahin, 2023).

Wind energy also can offer significant contributions, especially during periods when solar power is reduced. Together, these renewable sources can create a balanced and sustainable energy mix, capable of responding to the grid's demands while reducing reliance on fossil fuels.

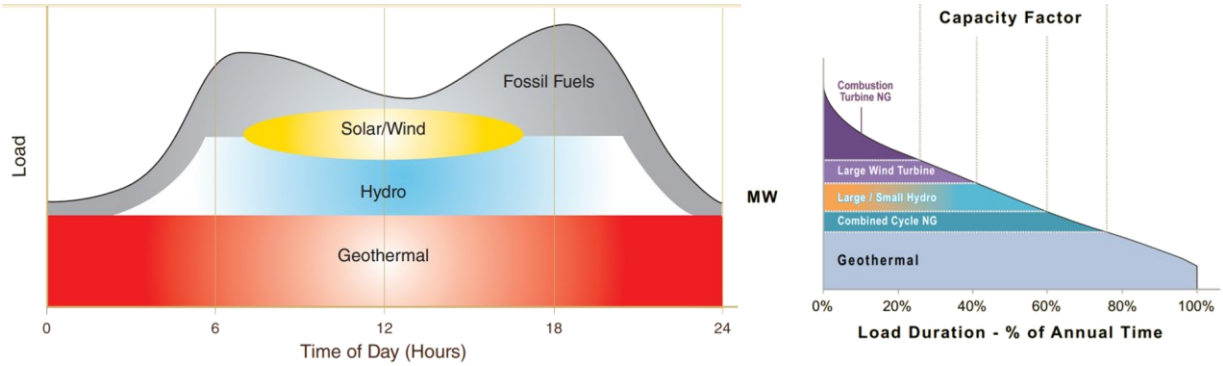

Figure 9: Simplified Load Curve vs Typical Fuel Sources. Modified from Gehringer & Lokhsa (2012).

The analysis of the load curve in conjunction with typical fuel sources highlights the importance of a diversified energy portfolio, with geothermal, solar, and wind energy playing distinctive yet complementary roles. Geothermal energy's reliability, coupled with the targeted contributions of solar and wind, provides a clear pathway toward a more sustainable and resilient energy future. As the world progresses towards cleaner energy solutions, the strategic integration of these renewable sources will be paramount in shaping an efficient and sustainable power generation landscape.

Furthermore, all three technologies present significant opportunities to reduce carbon emissions. Geothermal has a relatively low environmental footprint per MW of electricity generated with emissions primarily from construction and drilling activities, not from operational (Bošnjaković et al, 2019). However, it has potential local environmental impact, including land subsidence and water resources. Geothermal development project utilizes high water usage, primarily during drilling and workover operation, and it is also required for cooling tower in geothermal power plant. Geothermal energy stands out for its efficient land use compared to solar and wind installations of similar capacity, but the exploration area can be extensive (DiPippo, 2008). Sustainable resource management practices are essential to mitigate these impacts (IPCC, 2023a).

Meanwhile, solar and wind projects necessitate careful siting to mitigate impacts on land use and biodiversity. While they require significant land areas for utility-scale projects, which could pose challenges in densely populated regions, wind farms often offer dual land use opportunities for agriculture or grazing, minimizing their actual footprint (Goodale, 2018). However, landscape and wildlife can also be affected. Offshore wind has less visual impact and further reduces land use, but raises concerns about marine habitats (Goodale, 2018). Operational emissions are low in wind project (World Bank, 2011; Farr, H et al, 2021). The emissions come mainly from turbine manufacturing and installation and mitigation strategies are being developed (ESA, 2019). Once in the operational stage, wind farms produce no direct emissions, offering significant environmental benefits (GWEC, 2021). Wind energy installations also have a lower water usage, primarily used for cleaning panels and some in the manufacturing process.

Solar energy has a low emission during operation and contributes significantly to carbon emission reduction. Solar energy's modular or rooftop installations for residential use also have minimal footprints (NREL, 2022a; Silalahi & Gunawan, 2022). However, concerns regarding land use and lifecycle environmental impacts, including manufacturing, transportation, and disposal, are emerging in solar projects, prompting efforts to increase solar panel recycling (PVPS, 2021; NREL, 2022b; Bošnjakovic´, Santa, Crnac, & Bošnjakovi´c, 2023; EPA, 2023). Solar energy installations have a low water usage, mainly for turbine cooling in some designs and maintenance.

4. COST OF DEVELOPMENT BETWEEN GEOTHERMAL, WIND, AND SOLAR

The initial investment costs for renewable energy projects in Indonesia vary significantly depending on the technology. Geothermal projects, for instance, require substantial upfront investment primarily due to the high costs associated with exploration and drilling. However, once operational, geothermal plants benefit from relatively low operational and maintenance costs, and a high-capacity factor due to the consistent availability of geothermal resources.

In contrast, solar power projects demand a lower initial investment, largely due to the decreasing cost of photovoltaic panels and associated equipment. Solar projects can be deployed relatively quickly and are scalable,

allowing for incremental investments aligned with demand growth. Nonetheless, the operational costs, while lower than geothermal, include regular maintenance and potential panel replacement over time.

Wind power projects fall between geothermal and solar in terms of initial investment. The cost of wind turbines and the complexity of site development contribute to the initial costs. Operational expenses are moderate but can be higher in offshore settings due to the challenging environment and accessibility for maintenance.

When comparing the cost-effectiveness of these renewable energy sources, several factors are considered. Geothermal energy, despite its high initial cost, often delivers the best long-term returns due to its consistent base-load power generation capability. Solar energy is increasingly cost-competitive, with declining hardware costs and improving efficiency making it an attractive option, especially for distributed energy solutions. Wind energy's cost-effectiveness is highly site-dependent; in areas with consistent wind patterns, it can offer competitive long-term value.

5. CONCLUSION

The study conclusively identifies geothermal energy as the most viable option for immediate scale-up within Indonesia's renewable energy portfolio, due to its ability to provide stable baseload power and its relatively lower environmental footprint. The findings highlight Indonesia's substantial untapped geothermal potential, particularly along the Pacific Ring of Fire, with an estimated capacity of 23,060 MW. Despite this high potential, the current utilization is just over 10%, signaling a significant opportunity for expansion. Geothermal energy not only promises stable energy output but also brings considerable economic benefits, such as substantial employment opportunities and contributions to government revenue, surpassing those offered by solar and wind energies. The intermittent nature and higher land use requirements of solar and wind energies underscore the need for enhanced storage solutions and careful site planning to optimize their deployment without extensive ecological impacts. The conclusion drawn from this analysis is that, while all three renewable sources hold considerable potential, geothermal energy stands out as the most strategically advantageous for Indonesia, given its current capability and readiness for scale-up.

Table 1: Comparison of Development Costs and Levelized Cost of Electricity (LCOE) for Geothermal, Solar, and Wind Energy in Indonesia.

POINT OF COMPARISON	GEOTHERMAL	SOLAR	WIND
Global Trend Cost	**Slightly increasing,** IRENA (2022b) reports that LCOE for geothermal energy has increased by +6% from 2010 to 2022.	**Significantly decreasing,** IRENA (2022b) reports that Solar PV and Concentrated Solar Power (CSP) was decreased approximately -89% and -69% respectively from 2010 to 2022	**Significantly decreasing,** IRENA (2022b) reports that onshore wind and offshore wind was decreased approximately -69% and -59% respectively from 2010 to 2022
Trend Cost in Indonesia	**Slightly decreasing,** IESR (2023a) reports a slight increase in the LCOE range for geothermal energy, moving from **5.47 – 10.26** in 2019 to **3.56 – 12.06** in 2022.	**Slightly decreasing** IESR (2023a) reports a slight increase in the LCOE range for utility scale solar PV, moving from **5.84 – 12.34** in 2019 to **4.09 – 10.09** in 2022.	**Slightly decreasing,** IESR (2023a) reports a slight increase in the LCOE range for wind onshore, moving from **8.62 – 16.10** in 2019 to **3.92 – 18.77** in 2022.
Levelized Cost of Electricity (LCOE) Global	5.6 USDc/kWh in 2022	**Solar PV:** 4.9 USDc/kWh in 2022 **CSP:** 11.8 USDc/kWh in 2022	**Onshore Wind:** 3.3 USDc/kWh in 2022 **Offshore Wind:** 8.1 USDc/kWh in 2022
Levelized Cost of Electricity (LCOE) Indonesia	The levelized cost of electricity (LCOE) for geothermal energy in Indonesia ranging from 3.56 to 12.06 USDc/kWh.	The levelized cost of electricity (LCOE) for Solar PV Utility Scale in Indonesia ranging from 4.09 to 10.09 USDc/kWh.	The levelized cost of electricity (LCOE) for Onshore Wind in Indonesia ranging from 3.92 to 18.77 USDc/kWh.

POINT OF COMPARISON	GEOTHERMAL	SOLAR	WIND
	According to the latest updates by IESR, the refined LCOE stands at **6.79 USDc/kWh**, with capital expenditures (CAPEX) accounting for 6.65 USDc/kWh and operational expenditures (OPEX) comprising 0.74 USDc/kWh (IESR, 2024a; IESR, 2024b).	According to the latest updates by IESR, the refined LCOE stands at **5.79 USDc/kWh**, with capital expenditures (CAPEX) accounting for 4.92 USDc/kWh and operational expenditures (OPEX) comprising 0.87 USDc/kWh (IESR, 2024a; IESR, 2024b).	According to the latest updates by IESR, the refined LCOE stands at **7.47 USDc/kWh**, with capital expenditures (CAPEX) accounting for 5.45 USDc/kWh and operational expenditures (OPEX) comprising 2.01 USDc/kWh (IESR, 2024a; IESR, 2024b). Then, the offshore wind has LCOE around 11.31 USDc/kWh in 2022
Major Cost Component	In a geothermal project, the major cost components include the **EPC power plant**, which accounts for approximately 34-48% of the total project cost, and **drilling activities**, which represent about 33-51% of the total expense.	For solar PV project in utility-scale, the major cost components are the **PV Modules** that accounts are approximately 35 – 44% of the total project cost, followed by **Balance of System (BOS)** and **Installation labor cost** that account 12 – 26% and 15 -26% respectively	Both in onshore wind and offshore project, the largest cost component is the **Wind Turbine** component that accounts approximately 27.6 – 55.4% from the total project cost. The second largest cost component is typically **substructure and foundation** that account 13 – 27.7% of the total project cost.

INSAN SMART - APIForestry and Natural Forest Succession Approach to Achieve Sustainable Community-Based Forest Restoration

Muhammad Riyadhi, M. Panji Pranadikusumah, and Iqbal Abi Yaghsyah

Star Energy Geothermal Darajat II, Limited

m.riyadhi@starenergy.co.id

Keywords: biodiversity, forest conservation, geothermal energy, social innovation

ABSTRACT

Geothermal Power Plant is one of the Power Plants that embraced forest to maintain the power supply sustainability. Located partly in Taman Wisata Alam Gunung Papandayan (Nature Park) and Darajat Protected Forest in Garut Regency, West Java, Indonesia, Star Energy Geothermal Darajat (SEGD) has always been in effort in maintaining the forest surrounding the facilities. The objective of this study is to descrobe the performance of INSAN SMART, a sustainable community-based forest restoration project at Cigupakan Area with apiforestry approach and by simulating natural forest succession. The study shows high level of trees survival rate and biodiversity while providing livelihood to the community.

1. INTRODUCTION

Forest encroachment is a global issue that has yet to be solved. Rapid industrial development causes land clearing for conversion to other uses to occur at an alarming pace. The loss of forests can lead to the loss of ecological services such as clean water, clean air and flood prevention. Forest lost also affect ecological services provided by biodiversity such as natural pollination, natural pest control and resources provider. These ecological services often forgotten and deemed not important, although in fact it is as much important as the industrial development itself. Without the services and the resources provided by nature, it is impossible for the industrial activity to run.

Although forest restoration effort always being promoted, the forest area that were lost doesn't get better in fact it keeps getting worse. This is because ecosystem recovery takes a long time which cause forest lost rate is always faster than forest recovery rate. In addition, social issues contribute to the obstruction of the ecosystem recovery process. People with low economies tend to live with nature and take resources from nature directly. The local often utilize natural resources from nearby forest, resources taken include clean water, goods such as wildlife and woods, etc. In addition, the community is also encroaching forest areas to be used as agricultural land. Even though the government already made a regulation on land usage the locals won't budge. Efforts to educate the community to leave the protected areas alone or adopt agroforestry farming systems have been fruitless. The community believes that vegetable crops are more profitable and has faster capital turnover. Therefore, there is a need for an innovative planting system that generates profits but does not damage the forest.

INSAN SMART is an ecosystem restoration program conducted by Star Energy Geothermal Darajat II, Limited. This program adopts an apiforestry system, which is a combination of bee cultivation (*Apis cerana*) with production crop cultivation in the form of stands. Some types of plants planted are pioneer plants, fruit plants and native plants of Mount Papandayan. Honey cultivation was chosen because the process does not require land clearing, on the contrary, honey cultivation requires a lot of flowering plants as food for bees to produce honey. In the process, this program is in collaboration with the Darajat Honey Forest Farmer Group and is supported by BKSDA.

The purpose of this paper is to describe the results of the INSAN SMART program. This paper will describe the efficiency of the apiforestry program and its implementation in the field. Hopefully this program will encourage successful reforestation program all around the globe.

2. METHOD

2.1 Study Site

Research was conducted from August 2022 to March 2024 in a Darajat Geothermal Power Plant located in Pasirwangi Village, Garut, West Java, Indonesia (coordinate 07°11'09"- 07°15'40"S and 107°41'54"-107°45'40"E). The study location is specified to piece of land within an area called Cigupakan. This 1.8 ha area is part of Star Energy Geothermal Darajat operation area which the company decide to use this land as a reforestation zone. Darajat Power Plant is located within Taman Wisata Alam (Nature Park), Hutan Lindung (Protected Forest) and private land with elevation around 1740-2200 above sea level in a valley near Mount Kendang which is part of Papandayan Mountains.

Figure 1: Forest Restoration Site.

2.2 Procedure

Participant observation method with action research approach were used to collect the Data. Data were collected directly while the observer themselves participated on the event. The subjects are not aware that they are being watched (Ugwu et al, 2023). The program is consisted of planting trees, trees maintenance and beehive installation. All activities are being observed and recorded.

2.3 Data Analysis

Data were analyzed using Interpretative phenomenological analysis. Data then presented using qualitative descriptive approach. The presentation of data from a qualitative descriptive study involves a straight forward descriptive summary of the informational contents of the data that is organized in a logical manner (Jiggins et al., 2016).

3. RESULT AND DISCUSSION

One of the environmental problems in Darajat is the shrinking forest area. The depletion of forest area occurs mostly in protected forest areas. Although protected forest regulation requires the land utilization to use an agroforestry system by combining production crops with tree stands, in practice there are many garden areas that use a homogeneous plantation system. Some types of crops grown by the community include cabbages, potatoes, carrots, chillies and other annual crops.

Homogeneous planting systems cause many environmental problems. This is because homogeneous planting systems cannot accommodate many diverse types of fauna that are useful for maintaining environmental balance (Vellend et al., 2007). The lack of canopy cover in the plantation area results in a lack of water infiltration and increases soil erosion by water (Yücesan et al., 2019). The steep slope adds to the high runoff rate of rainwater that causes erosion in the plantation area and increases the potential for flooding in the Garut City.

Efforts have been made to replant the plantation to restore its function as a protected forest. However, these efforts have been fruitless. The reason is that every time planting is carried out in the plantation area, the plant seeds that have been planted will be plucked after a few days of planting. Some of the factors that cause the loss of these seedlings are the lack of care and supervision of the seedlings. It is not uncommon for seedlings to be deliberately uprooted because it is considered that they will block the sunlight from the vegetable plants and cause the quality of the harvested vegetables to be less than optimal. The slow-growing nature of tree species makes it difficult to monitor tree growth.

Based on these problems, it can be concluded that innovative reforestation efforts are needed that use fast-growing tree species, intensive supervision and care of seedlings and agroforestry systems that provide profit for the locals. The Apiforestry system was chosen for the implementation of the reforestation programme in the Darajat

Geothermal area. The Apiforestry system is a combination of a beekeeping system with an agroforestry system. In the implementation of the INSAN SMART programme, the community, namely the Kelompok Tani Hutan (KTH) Madu Darajat Berkah and the government agency, namely the West Java BKSDA Seksi Konservasi Wilayah (SKW) V, ensure the success of the programme.

3.1 Reforestation Program

The reforestation programme in this study uses a system that replicates the natural succession process in nature and accelerates it. Succession is a process of change in ecological and environmental aspects that continues regularly over a period of time and forms new biodiversity communities. Succession is a long process that takes a long time. Natural succession couldn't keep up with the rate of forest destruction, where the forest recovery rate is slower than the forest destruction rate. It is hoped that accelerating the succession process can increase the success rate of forest reforestation programmes.

Succession replication is carried out by planting local plants in the Mount Papandayan Nature Reserve combined with fast-growing plants we called pioneer plant. The planting distance used is 4x4 meters where endemic plants planted in the middle (figure 2). The type of fast-growing plant used is Kibadak (*Alnus* sp). Kibadak plants were chosen because they have a fast growth rate. Kibadak will provide shade and protection to local plants that require longer growing time. Kibadak's shade cover will maintain soil moisture in the dry season and inhibit the growth of weeds that could potentially inhibit the growth of local plants (Isaac et al., 2024). After planting, the saplings are cared for by watering during the dry season, fertilizing and weeding. Plant growth is always monitored and recorded. In addition to local plants, production plants are planted that will become bee food for honey bee cultivation.

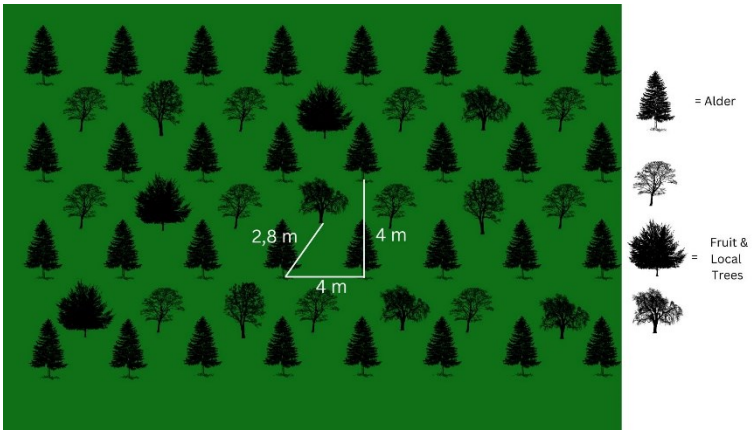

Figure 2: Planting model.

Restoration activity was carried out by SEGD together with KTH Madu Darajat Berkah, which is an organization assisted by BBKSDA West Java SKW V. This community organization deeply aware of the importance of protecting the environment. Members of KTH Madu Darajat Berkah often conduct reforestation and tree planting activities around Mount Papandayan. The restoration project was guided and supervised by BKSDA officers. Planting is carried out in the Darajat Geothermal Field area which is part of the SEGD Right of Way (RoW). Thus this restoration program is a collaboration of three institution.

The restoration program shows promising results. After 22 months after planting, the kibadak plants have reached an average height of 3 meters. Kibadak trees that were planted grows really well and there are no indications of plant uprooting by irresponsible parties. The presence of buffaloes grazing in the planting area did not hinder the growth and development of the kibadak plants. The fast-growing kibadak plants provide shade and shelter to the slower-growing local plants. The thick trunk and dense canopy make it difficult for buffalo herds to pass through the planting area. The dense canopy cover is also expected to inhibit the growth of grasses that require a lot of sunlight. Eventually the grasses in the planting area will disappear and reduce the buffalo's interest in visiting the planting area.

Some local plants have been planted in the Cigupakan area. Local plants were planted simultaneously with pioneer plants. Local plants continue to be added throughout the year. Local plants couldn't be planted in abundance number. This is because the availability of local plant seedlings is difficult to obtain. Because local seedlings have not been widely cultivated and most types of forest plants cannot be cultivated, planting local plants is mostly done by moving plant seeds from protected forest areas around the plantation. Currently, 30 types of local plants have been planted with the number as in the table 1.

Figure 3: Buffalo grazing at plantation area.

3.2 Bee keeping Program

In addition to the reforestation program, SEGD collaborated with KTH Madu Darajat Berkah and BBKSDA Jabar SKW V to develop a honey farm based on sustainability by combining it with an agroforestry system. This

program is carried out with the same institution as the reforestation program because this activity is part of a series of activities.

Honey cultivation is one of the activities of the Darajat community that has been carried out for a long time. There are two types of honey that are utilized by the Darajat local community, namely Odeng (*Apis dorsata*) & Nyiruan (*Apis cerana*). Odeng is a wild forest honeybee that cannot be cultivated. This honey bee has a large size nests placed in high branches. While nyiruan is a bee that comes from the forest, but this species has the characteristics of a smaller body size, likes to nest in weathered wood or in the ground and is more docile so that it is possible to be cultivated (Niem & Trung, 1999).

Honey farming was chosen because honey is one of the natural resources of non-timber forest products. Honey farming does not require large tracts of open land to operate, instead honey farming requires lush, overgrown land with food plants (flowering plants). In addition, pure honey has a high economic value, so honey cultivation is a business opportunity that generates high income but does not damage the forest. Members of KTH Madu Darajat Berkah understand this very well, therefore they are determined to carry out reforestation activities, especially by planting flowering plants such as red calliandra (*Calliandra calothyrsus*), *Xanthostemon Chrysanthus* and fruit plants.

KTH Madu Darajat Berkah is tasked with making bee boxes and finding bee colonies for cultivation. The honey box is made from wooden boards with a length of 30 cm, a width of 26 cm and a height of 40 cm. The top of the box can be opened to harvest honey and conduct colony checks. Inside the box, frames are placed as a place for bees to build nests that will later be used to store honey. In one honey box, 8-12 frames are placed. The honey bee used for honey cultivation is the A. cerana (Nyiruan) species.

The process of taking bee colonies is carried out by removing colonies from nature (such as in tree branches, dead wood and from the ground). Taking bee colonies begins with finding bee colonies in nature. The type of bee colony must be confirmed that the type is A. *cerana* and not A. *dorsata* which is a type of bee that cannot be cultivated. Once the bee colony is found, fumigation is carried out. Fogging is done to reduce attacks from bee colonies. Then the queen bee of the target bee colony is identified. Queen bees have a different morphology from worker bees. The queen bee is bigger in size . After identification, the queen bee is separated from the colony by putting the queen bee into a special container to avoid the escape of the queen bee. Then the queen bee is put into the box. Instinctively, worker bees will follow where the queen bee goes, so that when the queen bee is stored in the box, the colony will automatically enter the box. Then transfer the honeycomb containing honey, pollen and bee pupae into the box. Honey and Pollen serve as a food source for bee colonies. After the entire bee colony follows the queen into the box, the box is closed and moved to the beekeeping area.

During bee harvesting, KTH members will use safety equipment in the form of a bee veil to cover the head and face. Honeybee safety standards require honey harvesters to wear special clothing that covers the entire body of the person harvesting the honey. Bee stings can cause allergic reactions that cause hives and even shortness of breath (Rayamane et al., 2014). However, KTH members who do honey harvesting are used to bee stings. They often do not use special clothing to protect their bodies. If stung by bees, they will show mild allergic reactions such as rashes and inflammation around the sting marks.

Bee colonies can be harvested after two to four weeks, depending on feed availability. At the change of seasons, honey production is very high. This is because at the turn of the season many plants start to flower so the bees can produce a lot of honey. Honey is harvested by smoking the bee colonies first to reduce the stinging potential of the bee colonies. Then the honey box is opened while still being smoked. The frames inside the box are taken out and the honeycomb built on the frames by the bees is taken using a knife and placed into a container. Only half of the frames in the bee box are harvested. Over-harvesting can cause the bee colony to stress and leave the hive box.

In addition to relying on honey from cultivation, the group also collects honey from people who have honey boxes. In addition to A. cerana honey, the group also receives A. dorsata forest honey purchased from forest honey hunters. The profession of forest honey hunter is a side job that still exists in the Darajat area, this is because the Darajat area still has many beautiful forest areas. So it is possible for forest bee colonies to develop.

The honey collected will then be packaged into several products. The products sold are honey that has been separated from the hive and honey that is sold together with the hive. The collected honey will be stored in a large plastic overnight. The honey will flow out of the hive and gather at the bottom of the plastic. The separated honey will then be filtered using a 60 mesh filter cloth. The filtered honey is then packed into plastic bottles of various sizes. The packaging sizes used include 100 ml and 250 ml. Beehives that have been taken honey are sold as honey with hives.

The honey produced from the cultivation process has a variety of different flavor notes depending on the type of forage eaten by the honeybees. Forest honey and honey collected from other places have taste notes of coffee,

chayote and forest plants. Group-produced honey generally has a taste note of calliandra. The taste note of calliandra has a sweet, floral aroma and a very sweet taste and not too thick viscosity. It is generally bright yellow in color and clear.

Honey cultivation has many challenges in its implementation. Some of the problems faced are extreme weather changes, animal disturbances and human disturbances. Various efforts have been made to anticipate and overcome the impact of these challenges.

The Apiforestry activity program is an example of the implementation of 3 P (People, Profit & Planet) sustainability. The implementation of the 3 P's is in line with the Company's vision and mission of renewable energy, namely the sustainable use of natural resources. This is because renewable energy is highly dependent on renewable resources generated by ecosystem services.

4. CONCLUSION

Apiforestry activities are forest restoration activities that involve local communities. This program implements the 3 P concept, namely People, planet and profit. The implementation of the 3 P's allows forest restoration efforts to run sustainably. Some of the factors that led to the success of this program are as follows:

1. Planting is done in SEGD areas where intensive monitoring is possible.
2. Activities are carried out in collaboration with state institutions engaged in conservation and also community organizations that are passionate about forest reforestation efforts.
3. Planting uses a planting model that combines pioneer and local plants.
4. The apiforestry model generates economic benefits so that the community sees the benefits in forest management efforts.

Analysis of CO_2 Emission Intensity of Geothermal Power Plant: Case Study Star Energy Geothermal Darajat II, Limited

Muhammad Riyadhi and Micia Zaputi Rohimah

Star Energy Geothermal Darajat II, Limited

m.riyadhi@starenergy.co.id

Keywords: CO_2 emission intensity, geothermal energy, JAMALI, sustainability performance, sustainable energy

ABSTRACT

The renewable energy sector has developed in recent years, marking a turning point toward a greener energy future. Among other options, geothermal energy stands out as a promising solution, particularly for Indonesia. Geothermal energy utilizes natural energy sources, geothermal fluid, that are present within geothermal reservoirs. With its abundant geothermal potential reserves, Indonesia has the opportunity to utilize this resource to meet the nation's energy demand while simultaneously reducing the dependence on fossil fuels. The reliability of geothermal energy further enhances its appeal as a sustainable solution, offering consistent and dependable power over a long time. Geothermal energy generates minimal environmental impacts since it requires less land areas relative to other power plants. Since geothermal power plants only utilize geothermal steam, they emit less emissions during the process relative to fossil fueled power plants. Geothermal power plants generate minimal CO_2 because there is no fossil fuel-based combustion during the electricity generation. The primary emission contributors of geothermal energy are carbon dioxide (CO_2), hydrogen sulfide (H_2S), and ammonia (NH_3) since they are naturally present in the steam as Non-Condensable Gas (NCG). However, these emissions are lower compared to those from fossil-fueled power plants. Star Energy Geothermal Darajat power plant (SEGD) is a prime example of geothermal energy utilization in Indonesia. With a combined capacity of 274.5 MW, SEGD provides continuous electricity to the communities connected to the Java, Madura, and Bali (JAMALI) interconnection system. This study aims to analyze SEGD's CO_2 emission intensity and evaluate the company's sustainability performance. Utilizing a quantitative method, the study shows that SEGD has a CO_2 emission intensity that is lower than the JAMALI interconnection system, thus providing more sustainable energy.

1. INTRODUCTION

According to Ministry of Energy and Mineral Resources (2022), Indonesia is facing an increase in electrical energy demand, currently reaching 40 GW, with the highest demand coming from the Java, Madura, and Bali regions, accounting for 72.4% of this total in 2020. This growing demand is driven by economic growth, with annual projections indicating an increase of 5% to 6% in the years ahead. However, Indonesia still relies heavily on fossil fuels, predominantly coal and oil, to meet these energy demands. This situation is still likely to happen in the following years. Coal accounts for 61.5% of total electricity generation in Indonesia, while oil and biofuel contribute 6.20%. Gas makes up 16.8%, whereas new and renewable energy sources, despite their potential, currently represent a share of 15.5% (PwC, 2023). This new and renewable sector includes hydropower, geothermal, solar, wind, and other energy, all of which hold the potential to support a clean energy transition for the nation. Expanding new and renewable energy utilization represents a promising approach to growing energy demands while reducing the demand for and dependency on fossil fuels.

Indonesia's energy sector still relies heavily on fossil fuels as the primary source of electricity generation, a trend expected to persist well into the following years. As outlined by PLN (2021), coal-fired power plants are projected to increase by 35% from 134 TWh in 2021 to 264 TWh in 2030. Moreover, coal will contribute approximately 60% of the country's electricity generation mix by 2030. In the same period, gas utilization as an electricity generation source is also predicted to increase by almost half while oil use plummeted. Indonesia's dependence on fossil fuels will continue, reinforced by the planning and development of new fossil-fueled plants. This significant dependence on fossil fuel is primarily driven by its cost-effectiveness relative to alternative electricity generation methods. Besides that, the availability of fossil fuels within Indonesia and their compatibility with existing transportation infrastructure also contribute to their popularity in the energy sector.

The dominance of fossil fuels in Indonesia's energy sector has environmental consequences, including air emissions. Currently, the energy sector ranks as the nation's second-largest emitter of greenhouse gas emissions, with electricity generation alone accounting for over 40% of these emissions. Projections indicate this percentage could escalate to 58% by 2030 if the current situation continues. The main contributor of emissions emitted from the energy sector is coal power plants, particularly carbon dioxide. Among other power plants, coal-fired plants emit the highest proportion of emissions, accounting for up to 84.2% of the total emissions generated within the

sector. Oil and gas contributed roughly 11.3% and 4.5% of the emissions, respectively (IEA, 2023).

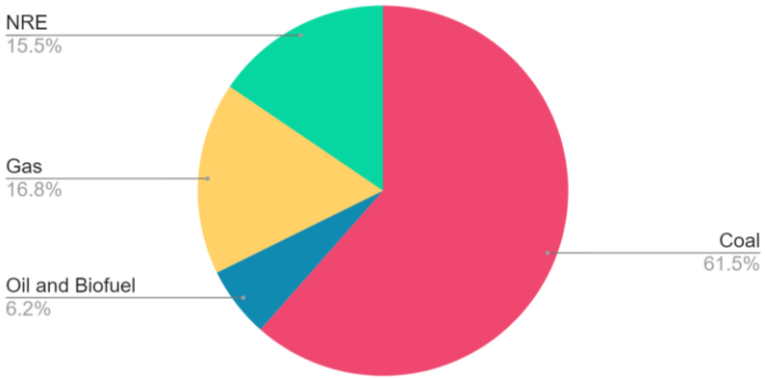

Figure 1: Indonesia's Electricity Mix Percentage in 2022.

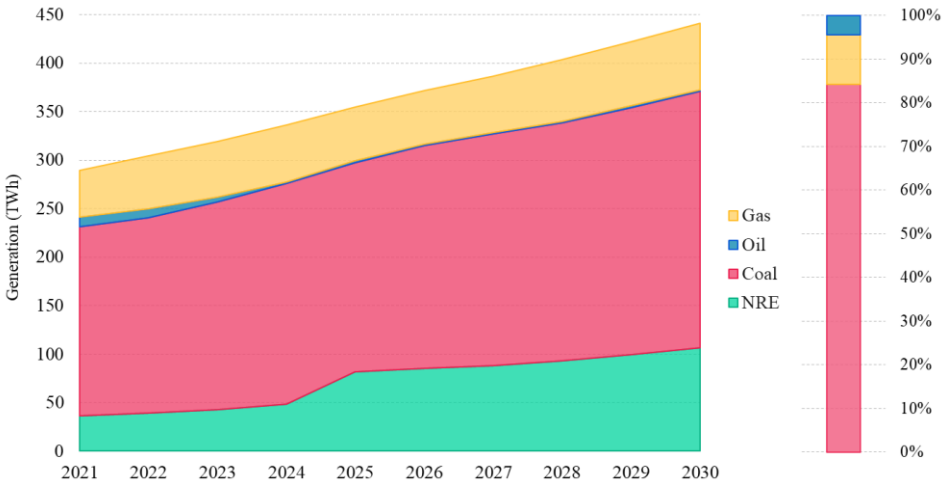

Figure 2: Indonesia's Electricity Projection and Percentage Share by Types.

Indonesia must accelerate its transition initiatives to cleaner energy to overcome this situation. Despite the nation's opportunity, new and renewable energy, including geothermal energy, is still underutilized in Indonesia. Indonesia has the largest geothermal potential globally, at 40% of the world's total reserves. Indonesia's geothermal resources and reserves are estimated at 23.6 GW, highlighting the country's immense capacity for geothermal energy production. It is composed of 5,714 MW speculative resources, 3,467 MW hypothetical resources, 9,575 possible reserves, 1,494 probable reserves, and 3,341.5 proven reserves, which spread on Sumatera, Jawa, Bali, Nusa Tenggara, Kalimantan, Sulawesi, Maluku, and Papua. Despite the big numbers, the actual utilization of geothermal energy in Indonesia currently stands at only 2,597.51 MW of installed capacity (MEMR, 2024). This shows that Indonesia has a lot of room to utilize its potential for further development of geothermal energy and reduce its reliance on fossil fuels.

According to Bertani and Thain (2002), geothermal power plants emit up to 7.5 times less carbon dioxide than fossil-fueled plants. This is because the electricity generation process does not involve fossil fuel combustion. Emissions from geothermal power plants mainly come from the steam, the raw material used for electricity generation, not from the process itself. This steam naturally contains carbon dioxide, along with a small amount of hydrogen sulfide (H2S) and ammonia (NH3). These gases are called Non-Condensable Gases (NCGs) because they are dissolved in steam and cannot be condensed. NCGs are typically vented from the power plant system since their presence affects the efficiency. However, the emissions released are lower than the greenhouse gases released during fossil fuel combustion (Fridriksson, 2016).

Star Energy Geothermal Darajat II, Limited (SEGD) is one of the leading players in the geothermal energy sector, focusing on sustainable energy production. SEGD's operational area covers two areas in West Java: Pasirwangi District, Garut Regency and Kertasari District, Bandung Regency. The company operates two power plants, Unit II and Unit III, with a combined capacity to generate 271 MW of electricity. SEGD operates under a joint operation contract with PT Pertamina Geothermal Energy. This collaboration involves supplying steam to the Unit I power plant, managed by PT Indonesia Power, and generating electricity from Unit II (95 MW) and Unit III (110 MW). The electricity produced is distributed through an interconnection system to reliably meet the energy demands of

communities in the Java, Madura, and Bali (JAMALI) regions. This study aims to analyze SEGD's CO_2 emission intensity and evaluate the company's sustainability performance.

2. METHOD

This research was conducted in two stages: first, calculation of SEGD's CO_2 emission intensity, and second, comparison of this intensity with the JAMALI interconnection system's CO_2 emission intensity. The emission intensity of SEGD was calculated using the methodology specified in Ministry of Environment and Forestry Regulation No. 21 of 2008, Attachment IX, regarding the reporting requirements for monitoring and measuring emissions from stationary sources such as geothermal power plants. Moreover, the calculation followed the guidelines agreed upon by the Indonesia geothermal power plant association for determining emission loads. The equation for calculating CO_2 emission intensity is as follows:

$$EI = \frac{Ms \times \%\, NCG \times \%\, CO_2}{MW} \quad (1)$$

where *EI, MW, %NCG, %CO_2* are emission intensity, generation (MW), steam flowrate (ton/hours), composition NCG in steam (%weight), and CO_2 fraction in NCG (%weight), respectively.

Subsequently, the obtained emission intensity of SEGD was compared with the CO_2 emission intensity of the JAMALI interconnection system, as reported by the Ministry of Energy and Mineral Resources (MEMR) in 2019. This comparison evaluates the company's sustainability performance. The data used in this study is secondary data with the permission of SEGD, including the amount of steam consumption, operational time, percent weight of NCG, total generated electricity, and percent weight of CO_2 emissions in NCG for unit II and unit III, averaged from 2020 to 2023.

3. RESULT AND DISCUSSION

SEGD is a geothermal energy company that operates two power plants, unit II and unit III, that utilizes steam as its primary energy source. Steam from the production well is first directed to a separator, which removes any remaining water. The high-pressure, dry steam from the separator is then channeled into the turbine, where it rotates the turbine blades to drive a generator and produce electrical power. A small portion of the generated electricity—4%—is used to operate the plant's equipment and for internal purposes, while the majority—96%—is supplied to the National Electricity Company (PLN) distribution network.Unit II and unit III each have a complete production setup, including a production well, scrubber, steam header, turbine, generator, main transformer, household transformer, condenser, gas removal system (GRS), cooling tower, and reinjection well.

The amount of greenhouse gas emissions produced by each geothermal power plant can vary depending on several factors, including the amount of steam consumed and the composition of the geothermal gases contained in the steam. In the context of geothermal power production, these gases are commonly referred to as non-condensable gases (NCGs) because they do not condense under the same physical conditions as water vapor but remain in the gas phase (Fridriksson, 2016). Generally, the composition of NCGs is dominated by CO_2. Other gases are typically present in low concentrations, ranging from a few percent to a fraction of a percent. Steam produced from the Dajat geothermal field contains approximately 0.45 to 0.5 percent NCGs. Of these NCGs, CO_2 constitutes, on average, about 94 percent of the total, according to sampling results conducted by SEGD. To determine the weight percent of CO_2 in the NCGs, the weight percent of NCGs and the weight percent of CO_2 are multiplied, as shown in Table 1.

In the context of calculating the CO_2 emission intensity of geothermal power plants, an assumption made is that all CO_2 present in the geothermal steam that enters the generation system is eventually released into the atmosphere through the cooling tower, along with water vapor. This assumption is made due to the process of simplifying emission calculations and focusing attention to the major emission parameter in geothermal power generation, which is CO_2 . It is important to note that this approach excludes certain minor sources of CO_2 emissions that might be present during the production process. For instance, fugitive CO_2 emissions that may occur during well testing activities, or small amounts of CO_2 that might be lost from the wells themselves, are not considered in this calculation. These sources are regarded as negligible in the context of this specific calculation, meaning they are considered to have a minimal impact on the overall CO_2 emission intensity (Fridriksson, 2016).

One method to calculate CO_2 emissions from geothermal power plants is through the analysis of steam flowrate data. The steam flowrate, expressed in tons per hour, represents the quantity of steam generated and supplied to the power plant for electricity production. This data is important in calculating the CO_2 emissions from the power plant. Steam contains trace amounts of CO_2 and by multiplying the steam flowrate by the percentage of CO_2 by weight in the steam, we the amount of CO_2 emitted can be known. Based on the calculation results, it is known

that the CO_2 flow rate emitted from SEGD's power plant facility ranges from 2.72 to 3.18 tons per hour. The CO_2 flowrate calculation results can be seen in Table 4.

Table 1: Percent weight of NCG in steam.

Year	%NCG (%weight)		
	Unit II	Unit III	Average
2020	0.463%	0.437%	0.450%
2021	0.483%	0.438%	0.461%
2022	0.556%	0.463%	0.510%
2023	0.502%	0.454%	0.478%

Table 2: Percent weight of CO_2 in NCG.

Year	%CO_2 (%weight)		
	Unit II	Unit III	Average
2020	94.99%	92.67%	93.83%
2021	95.00%	92.89%	93.94%
2022	95.21%	93.03%	94.12%
2023	95.41%	92.87%	94.14%

Table 3: Percent weight of CO_2 in steam.

Year	%CO_2 in steam		
	Unit II	Unit III	Average
2020	0.44%	0.40%	0.42%
2021	0.46%	0.41%	0.43%
2022	0.53%	0.43%	0.48%
2023	0.48%	0.42%	0.45%

Table 4: CO_2 flowrate.

Year	CO_2 Flowrate (ton/h)		
	Unit II	Unit III	Average
2020	2.51	2.90	2.72
2021	2.70	2.95	2.84
2022	3.08	3.07	3.12
2023	2.59	2.98	2.81

Table 5: Emission intensity of SEGD.

Year	Emission Intensity (ton CO_2/MWh)	
	Unit II	Unit III
2020	0.027	0.025
2021	0.029	0.026
2022	0.036	0.026
2023	0.028	0.026
Average	**0.030**	**0.026**

Emission intensity is an indicator used to assess the environmental impact of various production processes, including the electricity generation process. It is quantified by dividing the total carbon dioxide (CO_2) by the total amount of electricity generated over a specific period of time. Emission intensity is typically expressed in units of tons of CO_2 per megawatt-hour (tons CO_2/MWh) which represents the amount of CO_2 emissions emitted for each megawatt-hour of electricity generated. For instance, in the case of SEGD, the emission intensities of SEGD are 0.026 tons CO_2/MWh for Unit II and 0.034 tons CO_2/MWh for Unit III, respectively. Overall, when considering the emissions from both Unit II and Unit III combined, the emission intensity is calculated to be 0.056 tons of CO_2 per megawatt-hour of electricity generated. This combined emission intensity value provides an aggregate measure of the CO_2 emissions associated with the total electricity generation from these two units.

Emission intensity is a measure of how much greenhouse gas is emitted per unit of electricity generated. it is useful for comparison between different types of power plants, as it is independent of the source (McLean & Richardson, 2016). By offering a uniform unit of measurement, emission intensity enables a straightforward comparison across a range of power generation technologies and energy sourcesIt translates diverse emission profiles into a common unit, making it easier to evaluate and compare the environmental impacts of various

technologies and methods. Furthermore, we can better understand how effectively different energy sources contribute to greenhouse gas emissions relative to the amount of electricity they produce. Moreover, emission intensity serves as a tool for stakeholders, including policymakers, energy producers, and consumers, to evaluate the sustainability aspect of their electricity generation.

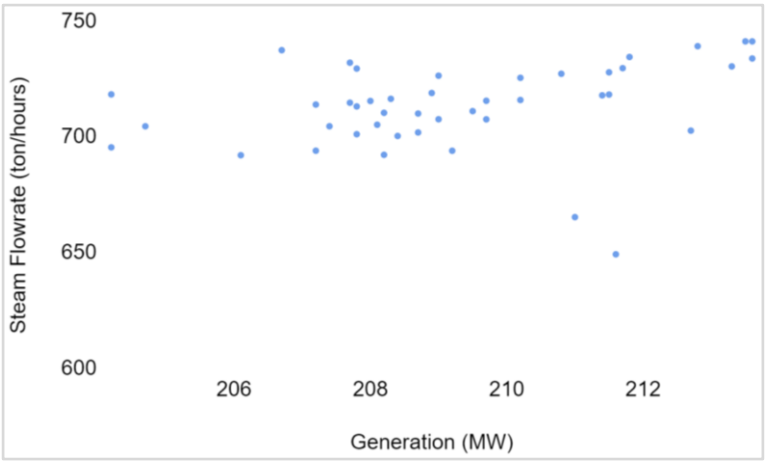

Figure 3: Steam flowrate and generation of SEGD.

To evaluate the company's sustainability performance, the value of the emission intensity of SEGD that has been obtained is then compared with the emission intensity of JAMALI interconnection system. This comparison can provide a clear understanding of the relative contribution of SEGD's CO_2 emissions to the overall emissions of the JAMALI electricity network. It also helps to understand whether the electricity produced by SEGD is a more or less sustainable option compared to others. According to the electricity system greenhouse gas emission factors in 2019, it is stated that the CM ex-ante emission intensity for JAMALI is 0.83 CO_2/MWh. ex ante refers to planning, forecasting, or decision-making activities carried out in advance of actual events. This approach helps optimize resources and manage risks. After comparison, overall, SEGD only shares 6.75% CO_2 emissions of the JAMALI interconnection system.

4. CONCLUSION

This study revealed that the overall CO_2 emission intensity of SEGD from unit II and unit III power plant is 0.056 ton CO_2/MW. With that, SEGD only share 3.36% CO_2 emission of the JAMALI interconnection system, thus providing more sustainable energy.

Keywords: Slimhole Drilling, Big Hole Drilling, Exploration Cost Management, Internal Rate of Return (IRR), Walkaway Costs – A unique concept analyzed in geothermal project risks

ABSTRACT

Indonesia, home to one of the world's largest geothermal reserves, is trying to expand its geothermal capacity to meet national energy demands and achieve sustainable development goals. The exploration phase, which serves as the foundation for subsequent project stages, remains critical to unlocking Indonesia's geothermal potential. However, high exploration costs and uncertainties present significant barriers to the financial viability of many geothermal projects. This paper examines the impact of these exploration costs on the economic feasibility of geothermal projects in Indonesia, focusing on the financial inefficiencies caused by varying cost management practices.

The paper presents a comparative analysis of two key exploration strategies: slimhole and bighole drilling. Using a hypothetical "Alpha" geothermal project case study, we simulate the financial outcomes of each strategy, highlighting their respective success rates, cost implications, and impacts on project cash flow and internal rate of return (IRR). The results show that slimhole drilling offers more favorable financial outcomes, reducing upfront costs and mitigating risks through incremental learning, though it presents trade-offs in data accuracy.

This paper identifies the key factors contributing to cost overruns and provides evidence-based recommendations for optimizing exploration expenditures, such as the use of reservoir numerical modeling during the exploration phase. Several strategies for planning drilling operations are also briefly discussed in this paper. These findings aim to guide policymakers and industry stakeholders in adopting standardized, cost-effective exploration practices to improve the financial viability and sustainability of Indonesia's geothermal projects.

1. INTRODUCTION

1.1 Geothermal Overview in Indonesia

Indonesia, gifted with one of the world's largest geothermal resources, is positioned as a potential global leader in geothermal energy development. Currently, the country has an installed geothermal capacity of approximately 2.4 gigawatts (GW), making it the second-largest geothermal producer in the world. However, this represents only a fraction of its estimated geothermal potential of 23.7 GW. The Indonesian government has recognized the strategic importance of geothermal energy in its energy transition efforts, aiming to diversify its energy mix and reduce greenhouse gas emissions. To this end, the government has set an ambitious target to increase geothermal capacity to 5.7 GW by 2030. Achieving these targets is crucial for meeting the rising energy demand sustainably and reducing reliance on fossil fuels.

1.2 Importance of Exploration Projects

Geothermal exploration projects are pivotal in realizing Indonesia's geothermal development targets. Most of the additional megawatts required to meet these targets are expected to come from newly explored prospect areas. Exploration is the critical phase in geothermal project development, where subsurface conditions are assessed to confirm the presence of exploitable geothermal resources. Proper management of exploration projects is essential for minimizing risks and costs, thereby enhancing the feasibility of subsequent development phases. Effective exploration practices can significantly reduce uncertainties, leading to more accurate resource assessments and better-informed investment decisions. Thus, optimizing exploration cost management is vital for all geothermal stakeholders, including government agencies, state-owned enterprises (SOEs), and private developers, to ensure the economic viability of geothermal projects.

Many published studies and papers have discussed the challenges the Indonesian government and the geothermal developers will face in developing geothermal projects in Indonesia (Ibrahim et al., 2005; IGA, 2014; Poernomo, 2015; Darma, 2016; Purba, 2018; Umam et al., 2018; Purba et al., 2019; Purba et al., 2020). Despite those challenges, the exploration phase is currently the most critical phase that Indonesia needs to take into action to seriously achieve the national geothermal target. Figure 1 shows that Indonesia has only been developing a few geothermal areas for geothermal power generation despite Indonesia's vast potential.

Figure 1 (Pusdatin ESDM, 2020) also shows Indonesia's distribution of geothermal areas according to each area's progress. Areas colored green, light green, and yellow indicate areas that have been through a preliminary survey, commonly the 3G survey. In some areas, the government, academic institutions, and geothermal developers have conducted surveys such as the temperature gradient hole or deep slim hole. Pink indicates the areas ready for development, whereas red indicates areas that have already been developed.

While Table 1 shows the list of the 22 geothermal prospect areas or concession areas still in the exploration stage and is expected to contribute to achieve the national geothermal target.

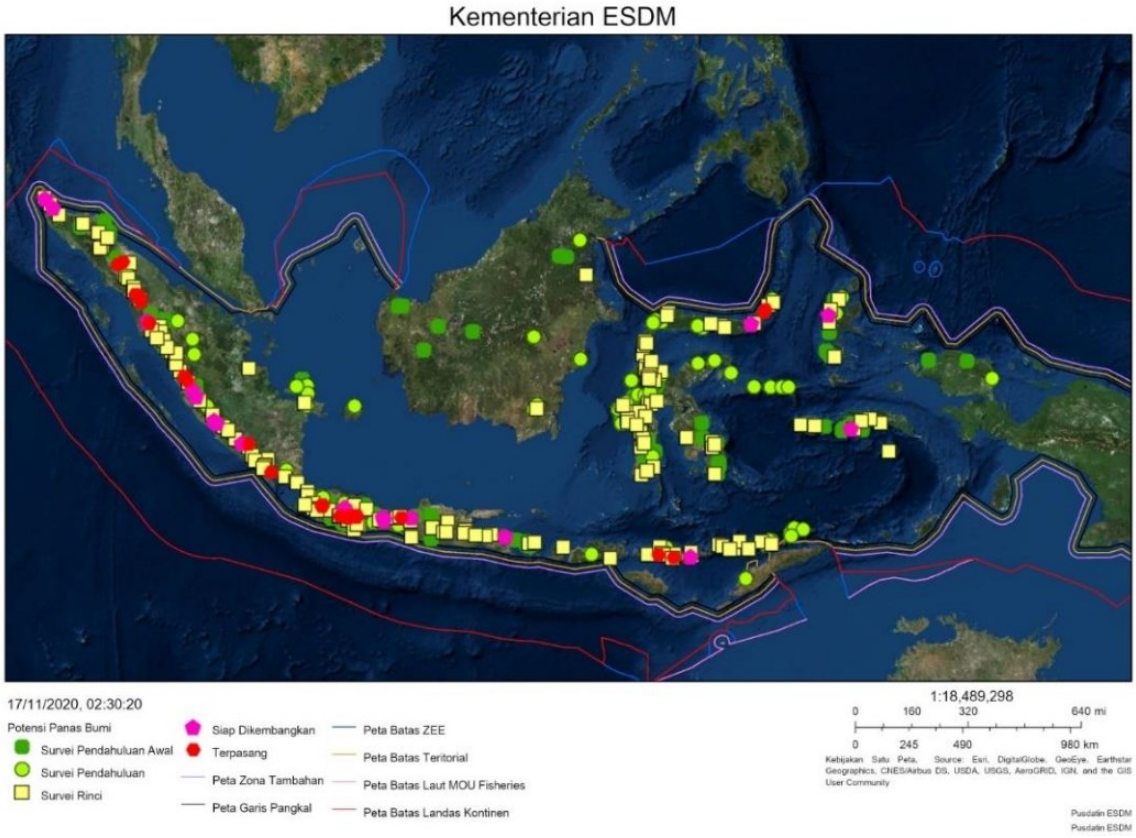

Figure 1: Maps of geothermal potential area in Indonesia with its status (Pusdatin ESDM, 2020).

The megawatt electricity (MWe) figures for each prospective geothermal area listed in Table 1 are estimates provided by the Indonesian government, typically based on initial exploration activities that rely on limited surface studies. These figures will be updated as more data becomes available, whether from more detailed surface surveys or drilling data. Table 1 also shows that even if geothermal stakeholders are only 50% successful in developing the areas listed, an additional 2,000 MWe could be achieved. When combined with the 2,400 MWe already installed, this would result in a total installed capacity of 4,400 MWe. While this still falls short of the national target, it brings the country significantly closer to meeting its goals.

1.3 Problem Statement

Understanding the importance of exploration in Indonesia, as discussed in the previous sub-section, the authors began to investigate deeper into why many exploration projects in Indonesia fail to meet expectations in terms of timeline and cost. One of the initial findings is that geothermal exploration projects are managed by various entities, including government agencies, SOEs, and private developers. However, there are clear indications of significant disparities in how these entities manage exploration costs. These differences stem from varying levels of expertise, resources, and strategic approaches to exploration. Some entities may lack the technical expertise or

financial discipline necessary for efficient cost management, resulting in overspending and economic inefficiencies. This inconsistency in managing exploration costs presents a major obstacle to the overall progress of geothermal development in Indonesia, potentially hindering the country's ability to achieve its ambitious geothermal targets.

This study then identifies several cases where high exploration costs have significantly undermined the economic feasibility of geothermal projects. It is hoped that this paper will encourage the geothermal community in Indonesia to take more serious steps toward formulating a comprehensive guide for developing exploration strategies tailored to the country's current geothermal prospects. Unlike the easier-to-explore fields of previous generations, today's geothermal areas present more complex challenges, requiring innovative approaches and strategic planning to ensure project viability.

1.3.1 Exploration Cost Challenges

By default, geothermal exploration in Indonesia presents significant financial challenges, with exploration costs being among the highest globally. This is primarily due to the complexity of drilling operations, the increasing difficulty of targeting viable well locations, and social and environmental hurdles. The high upfront capital required for exploration, combined with the financial risks associated with uncertain outcomes, often deters investment. These cost challenges can halt geothermal projects before they even reach the development phase, making it crucial to explore cost-effective strategies that can ensure the economic viability of such projects.

Indonesia's current geothermal prospects present far greater exploration challenges compared to earlier, more accessible fields. Unlike the geothermal areas previously explored, many of the remaining prospects exhibit minimal or no surface manifestations, making it harder to detect viable geothermal resources. Additionally, these fields are characterized by smaller resource sizes and low to medium enthalpy, further complicating exploration efforts. The difficulty in targeting optimal well locations is exacerbated by social and environmental issues, such as land use conflicts and community resistance, which can delay projects and increase costs. The relatively "easy" geothermal fields have been largely exhausted, and the conventional exploration approaches that worked in the past are no longer relevant for Indonesia's remaining prospects. In this evolving landscape, a shift in exploration strategy is essential, requiring more innovative, cost-effective, and adaptive methods to unlock Indonesia's remaining geothermal potential.

1.3.2 Current Exploration Strategies and Dilemmas

Choosing the appropriate exploration strategy is one of the key dilemmas faced by geothermal stakeholders in Indonesia. The decision between slimhole and bighole drilling, both widely used in the industry, presents a complex trade-off:

a. *Slimhole drilling* offers a lower-cost option, allowing developers to test multiple areas with limited upfront investment.However, the data obtained from slimholes may lack the depth and accuracy needed to fully assess the resource.
b. *Bighole drilling*, while providing more comprehensive and reliable data, comes with significantly higher costs and greater financial risk, especially in the exploration phase where success rates are uncertain.

Adding to the complexity, slimhole drilling remains relatively underutilized in Indonesia due to a long hiatus in exploration using this method and the limited availability of experienced contractors. This situation puts further pressure on developers to opt for bighole drilling, despite its higher costs, to ensure faster results that satisfy investor, and shareholder demands for early revenue and project completion.

1.3.3 The Need for Advanced Exploration Techniques

With the rapid advancement of computer technology, there is potential to enhance exploration accuracy and reduce costs by integrating advanced numerical modeling into the exploration phase. By combining static and dynamic models, stakeholders can improve the well-targeting process, quantify resource uncertainties, and optimize exploration strategies. However, the adoption of such technologies remains slow, largely due to perceptions of high upfront costs and long lead times. The need to incorporate more cost-effective exploration techniques, while managing financial risks, is critical for Indonesia to scale up its geothermal energy production.

At the time this study was conducted, the authors found that very few exploration projects in Indonesia, whether managed by private developers, SOEs, or government entities, were utilizing reservoir numerical modeling as part of the decision-making process. Unfortunately, many geothermal players are still stuck in an outdated mindset, believing that reservoir numerical modeling is difficult, expensive, and time-consuming. In reality, with advancements in technology, reservoir numerical modeling can now be completed in a matter of weeks or even days if the data is available in a standardized format.

1.3.4 Financial Inefficiencies and Walkaway Costs

Another major problem or dilemma in geothermal exploration is the financial inefficiency stemming from inconsistent cost management practices across different stakeholders—government agencies, state-owned enterprises (SOEs), and private developers. These inefficiencies can lead to excessive expenditure and unproductive wells, increasing the overall "walkaway costs" in cases of exploration failure. For example, bighole drilling failures carry significantly higher walkaway costs, sometimes amounting to hundreds of millions of dollars, which can severely impact the financial feasibility of a project.

Walkaway costs are often overlooked or underestimated by stakeholders in Indonesia because they require projects to be executed in stages rather than all at once. Considering walkaway costs is frequently interpreted by decision-makers as prolonging the project timeline to reach Commercial Operation Date (COD), which is seen as reducing the overall economic value of a project.

In summary, the high costs, strategic dilemmas, and technological gaps in geothermal exploration in Indonesia create a significant barrier to achieving the country's geothermal energy goals. Addressing these challenges requires careful planning, effective cost management, and the adoption of advanced exploration strategies to reduce financial risks and improve the likelihood of successful project outcomes.

1.4 Study Objectives

The authors' motivation for conducting this study and publishing this paper is to trigger discussions around the differences between the exploration and development phases, particularly in terms of resource uncertainties and

the importance of keeping CAPEX as low as possible from the earliest stages. The authors observed that, at the time of writing this paper, there was a tendency among geothermal exploration project implementers in Indonesia to overlook exploration cost planning in their rush to proceed quickly. Therefore, this paper aims to achieve several key objectives, as outlined in Table 2.

2. GEOTHERMAL EXPLORATION OVERVIEW

Understanding the criticality of the exploration stage is essential as it determines the feasibility and potential success of geothermal projects. This phase involves identifying viable resources, assessing their quality and quantity, and evaluating economic feasibility. Proper execution during exploration reduces risks, optimizes costs, and enhances project success. Without a solid foundation from thorough exploration, subsequent phases face increased uncertainties and higher costs. Recognizing this importance ensures stakeholders prioritize careful planning and resource allocation early in geothermal development.

2.1 Geothermal Exploration Regulation in Indonesia

Geothermal development in Indonesia follows a structured framework outlined in Law (Undang-undang/UU) No. 21/2014 and Government Regulation (Peraturan Pemerintah/PP) No. 7/2017. A comprehensive understanding of the regulatory framework governing the geothermal industry in a specific country, such as Indonesia, is essential as it directly influences project strategies, cost estimations and economic analysis.

Table 2: The study objectives.

No.	Objectives	Description
1.	To analyze the impact of exploration costs on the overall financial viability of geothermal projects through simulation of various scenarios.	This objective involves simulating both actual and hypothetical cases, such as the "Alpha Project," to explore the financial outcomes of different drilling strategies (e.g., slimhole vs. bighole). The study aims to assess how exploration expenditures, success ratios, and well targeting influence cash flow, internal rate of return (IRR), and other key financial metrics in geothermal projects.
2.	To identify the key drivers behind high exploration costs in Indonesia's geothermal sector.	This objective seeks to pinpoint specific factors that contribute to elevated exploration costs, such as technical challenges (e.g., difficult well targeting, low enthalpy resources), and inefficiencies in project execution. Additionally, it will examine the challenges posed by limited contractor availability and the financial implications of social and environmental issues.
3.	To compare slimhole and bighole drilling strategies and evaluate their cost-effectiveness in exploration and project development.	This objective focuses on providing a comparative analysis of slimhole and bighole drilling, as demonstrated in the "Alpha Project" simulation. It aims to identify the trade-offs between the two approaches in terms of cost, data accuracy, success rates, and risk mitigation, while highlighting the potential of slimhole drilling to reduce walkaway costs and improve project economics.
4.	To develop actionable strategies for reducing exploration costs and improving the financial feasibility of geothermal projects in Indonesia.	Based on the findings, this objective will outline evidence-based recommendations and best practices to help stakeholders—government agencies, SOEs, private developers—optimize exploration expenditures. The strategies will include integrating advanced modeling technologies, improving exploration planning, and adopting standardized cost management practices to enhance the overall economic viability of geothermal investments.

Table 3 summarizes these regulations that delineate the various stages involved in the development process. Familiarity with these regulations is vital to promptly identify any potential conflicts between local regulations and the guidelines established by international financial institutions. Such early recognition ensures alignment with the prescribed regulatory requirements, enabling smooth project implementation and adherence to international standards.

Table 3: Geothermal development stages in Indonesia (modified from Adityatama et al., 2020; Siahaan et al., 2023; Direktorat Panas Bumi, 2022).

Geothermal Development Stage	Description	Eligible institution conducting the activity	Duration
Preliminary Survey	Identify areas with potential geothermal resources and conductsurveys to gather information on the geology, geochemistry, and geophysics of the area. The result from the survey is then being integrated to develop conceptual model, resource assessment, and well targeting.	Government/Business Entity/State-Owned Enterprise	1 year
Exploration and Feasibility Study	Proving a geothermal resource exists and proving/delineating sufficient reserves for development. Once a viable resource has been identified, the resource assessment phase begins. This includes determining the size of the resource and the potential for energy production. Engineers will also conduct various studies such as environmental impact assessment, social impact assessment, and feasibility study.	Government/Business Entity/State-Owned Enterprise	5 + 1 + 1 years
Development and Construction	Proving that development of the resource is technically and economically feasible by drilling production and injection wells. Constructing the geothermal facility on specification, on time and on budget.	Business Entity/State-Owned Enterprise	2-4 years
Operation and Maintenance	After the construction of the power plant is finished, it will be operated and maintained. The operators will monitor the power plant's performance, make repairs and improvements as necessary, and ensure that it is operating in compliance with relevant regulations.	Business Entity/State-Owned Enterprise	30 years

2.2 Geothermal Exploration Objectives

Geothermal exploration projects are integral to the development of geothermal energy resources. They are designed to assess the viability of a site for geothermal energy production, ensuring that subsequent development phases are based on solid scientific data and economic analyses. The primary objectives of a geothermal exploration project can be categorized into three main areas: identification of geothermal resources, resource assessment, and feasibility evaluation.

1. **Identification of Geothermal Resources**. The foremost objective of any geothermal exploration project is the identification of geothermal resources. This involves confirming the presence and extent of subsurface heat sources, which are typically located in areas with volcanic activity or tectonic plate boundaries. During this phase, exploration teams employ various geophysical and geochemical methods to detect anomalies that indicate geothermal activity. Techniques such as remote sensing, seismic surveys, magnetotelluric (MT) surveys, and soil gas sampling are used to gather preliminary data about the geothermal potential of a site. The goal is to delineate areas with high temperature gradients, which suggests the presence of significant geothermal reservoirs. Accurate identification is crucial as it lays the foundation for more detailed studies and reduces the risk of unsuccessful drilling.
2. **Resource Assessment**. Once a geothermal resource is identified, the next objective is to assess the quality and quantity of the resource. This involves a detailed evaluation of the geothermal reservoir, including its temperature, pressure, permeability, volume, and fluid chemistry. Exploratory drilling is a key activity during this phase, where test wells are drilled to obtain direct measurements from the reservoir. The data collected from these wells, including temperature logs, fluid samples, and pressure readings, are analyzed to estimate the potential energy output of the geothermal resource. The assessment also involves reservoir modeling and simulation to predict the behavior of the reservoir over time under various production scenarios. This comprehensive evaluation helps in determining the sustainability of the resource and its capacity to support long-term energy production.
3. **Feasibility Evaluation**. The final objective of a geothermal exploration project is to evaluate the economic feasibility of developing geothermal resources. This involves a thorough cost-benefit analysis, considering both the capital expenditure required for development and the potential revenue from energy production. Key factors in this evaluation include the costs of drilling, construction of power plants, infrastructure development, and ongoing operational and maintenance expenses. The feasibility study

also examines the potential market for geothermal energy, including electricity prices, demand forecasts, and potential off-take agreements. Environmental and regulatory considerations are also factored into the economic analysis, as compliance with environmental regulations and obtaining necessary permits can impact project timelines and costs. Ultimately, the feasibility evaluation aims to determine whether the geothermal project can deliver a satisfactory return on investment, guiding decision-makers on whether to proceed with development.

2.3 Risks in Exploration Phase

Geothermal exploration can be challenging, as it involves identifying and assessing the potential for geothermal resources in a specific area. The fundamental objective of a geothermal exploration program is to identify and characterize a geothermal resource that can be economically developed by applying an optimized design based on the exploration results.

Therefore, it is common for geothermal developers or investors to face dilemmas with making investment decisions in the exploration stage. The difficulty is created by the requirement to spend high upfront capital but relying on information that is still very minimal and has a very high level of uncertainty. Additionally, the most significant cost component of an exploration project comes from the drilling activities and the construction cost of supporting infrastructures such as access roads, well pads, and other supporting facilities. This portion could significantly impact on the total project costs if not planned and managed correctly.

The main challenges of geothermal exploration in Indonesia are summarized as follows (IGA, 2014; Poernomo, 2015; Darma, 2016; Purba, 2018; Umam et al., 2018; Purba et al., 2019; Adityatama, 2020; Purba et al., 2020; Purba et al., 2021a; Purba et al., 2021b; ADB, 2015; Utami, 2010):

1. **Difficulty in locating the "hottest area"**: Geothermal resources are not always visible at the surface and can be challenging to locate without conducting detailed geological, geochemical, and geophysical (3G) surveys and drilling test wells. The unclear indications or thermal manifestations from surface studies can make it challenging to identify the most promising areas for exploration and increase the risk of drilling "dry" wells.
2. **High exploration costs**: Conducting 3G surveys, developing a reliable conceptual model, and drilling test wells can be expensive, and there is always the risk that a project will not yield a viable resource. The high upfront capital and resource uncertainties can make it difficult for developers to secure funding for exploration activities. Indonesia is currently known as one of the most expensive countries for geothermal drilling, with costs ranging from 2,900 to 4,000 USD per meter. In the exploration phase, drilling costs per well are generally higher than during the development phase.
3. **Complex geology**: Geothermal resources in Indonesia are mainly located in a volcanic area with complex geological environments, making it difficult to understand the subsurface conditions and identify the most promising areas for exploration. The difficulty of assessing geological and subsurface conditions is further compounded by the shortage of experienced geoscience personnel with strong foundational knowledge of Indonesia's geothermal geology.
4. **Lack of direct and reliable data**: In some cases, there may be a need for more data on the geology and geochemistry of an area, making it challenging to identify potential resources and plan the exploration activities. Currently, an increasing number of geothermal prospects in Indonesia are considered "blind systems," meaning there are little to no surface indications or manifestations that provide information about the reservoir. This greatly increases the exploration risk, as project license holders must proceed with exploration drilling based on very limited data.
5. **Environmental impacts**: Exploration activities can have various environmental impacts, such as air and surface water pollution, soil degradation, hazardous noise, release of hazardous gases, landslides, deforestation, and the potential for groundwater contamination. Mitigating these impacts can be costly and time-consuming.
6. **Social and community issues**: Exploration activities can also have social and community impacts, such as displacement of local communities and land-use conflicts. Developers need to address these impacts and engage with local communities to ensure their support and minimize the risk of project delays or cancellations. This aspect is often overlooked during exploration drilling planning, where project owners assume that all the land needed for drilling can be easily acquired. As a result, they often fail to prepare proper contingency or mitigation plans.
7. **Uncertain regulations**: Geothermal exploration is subject to various national, regional, and local regulations. The uncertainty can make it difficult for developers to navigate the regulatory environment and can increase the risk of project delays or cancellations. One of the long-standing issues is the regulation of geothermal electricity tariffs and the risk-sharing mechanism between the government and private or state-owned developers in the exploration phase.

Given the high uncertainty and risks involved in the exploration stage, most commercial lenders are still reluctant to provide financing facilities for this purpose. Even international financial institutions (IFI) are reluctant to fund up-front exploration and typically will provide financing only once 50% or more of the steam resource is proven (Asian Development Bank and The World Bank, 2015). With this consideration, exploration drilling generally requires the sponsor's equity, which may only be recovered if the drilling reveals that the resource is technically sufficient and economically viable for exploitation. Meanwhile, from the developers' point of view, to mobilize the up-front equity needed for exploration, they will also consider the adequacy of the tariff, which adds to the challenges faced by the developers given the single buyer model applied in Indonesia.

One way that GoI has taken to tackle the challenges in the exploration stage is by launching the Infrastructure Financing for Geothermal Sector fund / Pembiayaan Infrastruktur Sektor Panas Bumi ("PISP Fund") through PT Sarana Multi Infrastruktur (Persero), as stipulated in the Minister of Finance Regulation No. 80 in 2022. This solution can be an alternative funding scheme that the developers may consider financing their exploration program, of which the typical funding application process will be described in sub-section 5.4 in this paper.

2.4 Cost of Geothermal Exploration in Indonesia

The cost of geothermal exploration in Indonesia can vary significantly, as it is contingent upon project-specific factors and the chosen exploration drilling strategy. An estimate of exploration costs is presented in Table 4, providing an overview of the anticipated expenses associated with conducting geothermal exploration drilling.

Table 4 illustrates the sequential stages involved in the execution of an exploration project, encompassing a range of activities that are conducted progressively, beginning with low-cost data collection attempts. Following the initial data collection, developers can proceed with activities that entail more significant investments if the results exhibit positive indications of geothermal potential. Notably, Table 4 provides a distinct representation of the climax of all exploration activities, which is the drilling of deep wells. This activity incurs the highest costs within the exploration stage.

It is important to note that the costs outlined in Table 4 are subject to variations based on multiple factors, including the depth and complexity of drilling, geological conditions, logistical considerations, and local context. Therefore, the figures provided should be regarded as approximate and indicative rather than absolute values. Additionally, the cost estimates in the rightmost column of Table 4 show a wide range, primarily due to the lower costs of slimhole drilling and the higher costs of bighole drilling, especially when infrastructure is required in areas with challenging terrain and logistics. Furthermore, incidents such as stuck pipe during bighole drilling can cause significant cost increases.

The tabulated information underscores the systematic progression of exploration efforts, whereby preliminary activities with relatively lower expenses pave the way for more resource-intensive undertakings. The delineation of cost variations among the stages underscores the significance of cautious financial planning and decision-making in geothermal exploration initiatives. By comprehending the cost implications associated with each stage, developers can effectively allocate resources and assess the financial feasibility of progressing further in the exploration process.

2.5 Differences between Exploration and Development Stages

2.5.1 Resource risk levels and drilling success criteria in the exploration and development stages

Managing a geothermal exploration project with a development mindset is risky because exploration aims to confirm resource viability with minimal costs. Prematurely adopting a development approach can lead to excessive financial waste, as significant infrastructure and operational investments may be made before confirming the resource's adequacy. This approach can jeopardize the project's economic feasibility, inflate costs, and lead to substantial financial losses. Prioritizing cautious, cost-effective exploration is crucial to avoid overcommitting resources and encountering unforeseen challenges, ensuring the project's long-term success and sustainability.

Therefore, it is crucial for decision-makers in geothermal energy development projects to understand the differences between the exploration and development phases from various perspectives. Table 5 illustrates the distinctions between geothermal projects in the exploration phase and those in the development phase.

2.5.2 Comparison of Drilling and Power Plant Construction Difficulties

As discussed in Table 4 and Table 5, drilling activities, particularly during the exploration phase, account for a significant portion of costs and are associated with high uncertainties. Figure 2 illustrates the comparison between the cost portions of drilling and power plant construction relative to their difficulty levels, helping decision-makers understand the nature of risks associated with these activities.

Table 4: Cost estimate of geothermal exploration drilling (modified from IGA, 2014; GeothermEx, 2010; Purwanto et al., 2018; Purba et al, 2019; Purba et al., 2020; Adityatama, 2020; Purba et al., 2021a; Purba et al., 2021b; Kristianto, 2018; Jacobs, 2022; Utami, 2010; GGGI, 2023).

Activity	Geology survey	Geochemistry survey	Geophysical survey	Initial conceptual integration and well targeting	Exploration drilling
Activity Description	Geological mapping on an area of 400 km^2. The work package including pre-field-work study, rock sampling and identification, structural mapping, and reporting.	Work package including a pre-field-work study, liquid and gas sampling from 30 locations, laboratory analysis and reporting.	Work package including pre-field-work study, 100 MT stations and 150 Gravity stations, interpretations, and reporting.	Integrate all report from 3G surveys to create several scenarios of conceptual models, including peer review.	Using 3 (three) standard/big hole type or 5 (five) slimhole type or combination of 2 (two) slimholes and 1 (one) full-size well. The cost estimate includes infrastructure construction cost to support the drilling operation. The duration estimate includes procurement process, preparation, equipment mobilization, drilling, well testing and demobilization.
KrisEstimated Duration	4-8 months	4-8 months	4-8 months	3-6 months	18 - 36 months
Cost Estimate (USD)	300,000 – 700,000	200,000 – 400,000	1,000,000 – 2,000,000	100,000 – 200,000	15,000,000 – 50,000,000
Considerations	Accuracy might be affected by terrain, weather, and field personnel experiences.	Accuracy might be affected by sampling method (minimize contamination) and laboratory competences.	Accuracy might be affected by noise during data acquisition anddata processing method, including personnel interpretation.	Accuracy might be affected by 3G data accuracy and personnel experiences and interpretation.	Deep wells, whether slimhole or bighole, allow the exploration team to acquire direct downhole data from the reservoir, providing valuable insights for more accurate resource assessment. However, this approach requires significantly more time and higher costs compared to 3G surveys.

Table 5: Distinctions between geothermal projects in the exploration phase and those in the development phase (GGGI, 2023; IGA, 2014; Purba et al., 2019; Purba et al., 2021a; Purba et al., 2021b).

Aspect	Exploration Stage	Development Stage
Primary Objective	The primary objective of the exploration phase is to prove the existence of a geothermal resource by gathering comprehensive information on the reservoir's characteristics, including temperature, pressure, permeability, geology, and chemistry. This phase typically begins by identifying and drilling in the most promising areas, or "sweet spots," to maximize the chances of success.	The primary objective of the development phase is to develop and exploit the confirmed geothermal resource for energy production. This involves drilling sufficient wells to meet the project's megawatt (MW) target and achieving the Commercial Operation Date (COD).

Aspect	Exploration Stage	Development Stage
Level of the Resource Risk	Very high due to: 1. The possibility of not finding a viable geothermal resource despite significant investment 2. Uncertainty about the reservoir's capacity, temperature, permeability, pressure, and sustainability.	Low to medium, with several points of considerations: 1. Over-extraction of the geothermal fluid can deplete the resource faster than anticipated, affecting the long-term viability of the project. 2. Proper reinjection of the spent geothermal fluid is crucial to maintain reservoir pressure and sustainability. Challenges in reinjection, such as blockage or inadequate reinjection wells, can affect resource longevity. 3. Improperly managed reinjection can lead to thermal breakthrough, where cooler reinjected fluids prematurely reach production wells, reducing overall thermal efficiency.
Typical Activities	Preliminary survey, surface studies / 3G surveys, preliminary environmental and social assessment, exploration drilling, resource assessment.	Additional surface studies after exploration drilling, Feasibility Study, Financial Close, Appraisal and Development Drilling, Power Plant and SAGS construction, COD, Further Resource Assessment, Reservoir Management
Well / Drilling Success Definition	Success for an exploration well is defined by obtaining positive outcomes, specifically identifying a viable geothermal resource with indicators that suggest it has development potential.	Success for development wells is defined by the establishment of suitable production and injection wells that can be effectively utilized in the production and injection strategy of a geothermal development project.

This is important to discuss in this paper because the authors observed that some geothermal investors in Indonesia still view power plant construction as riskier than drilling activities. This might be true if the power plant is procured and built before the geothermal resource beneath the surface is confirmed. In such cases, there is a risk that the plant's installed capacity may exceed the geothermal reservoir's ability to supply sufficient hot water or steam to the surface.

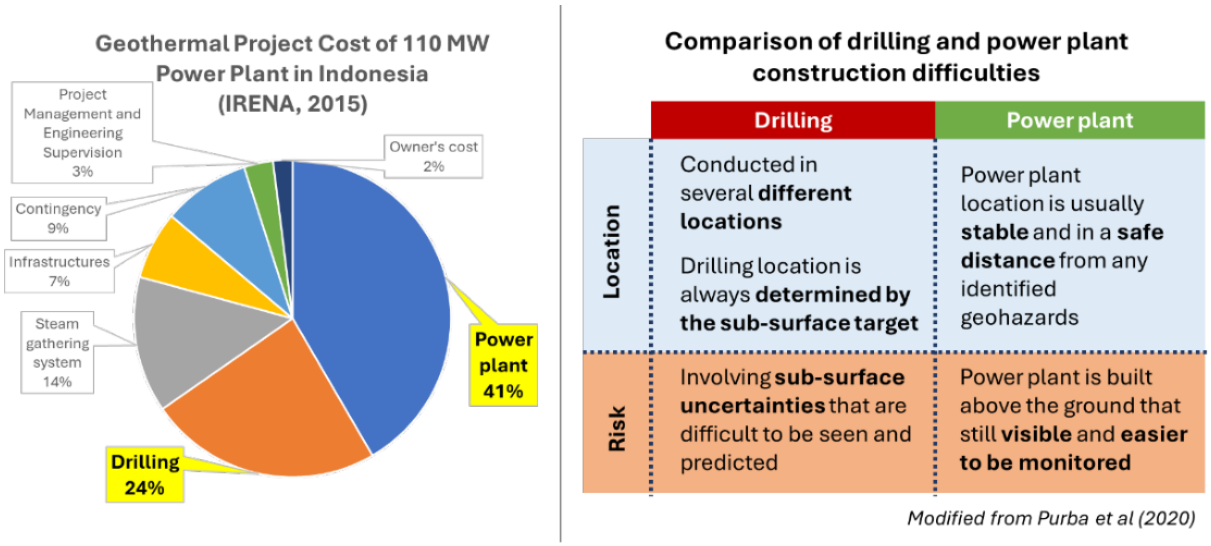

Figure 2: Comparison of Costs and Difficulty Levels Between Drilling Activities and Power Plant Construction in Geothermal Projects (IRENA, 2015; Purba et al., 2019; Purba et al., 2020; Purwanto et al., 2018; Utami, 2010).

3. IMPORTANCE OF CAPEX IN GEOTHERMAL PROJECTS

Capital Expenditure (CAPEX) is a critical component in the financial planning and economic assessment of all projects, including geothermal. Understanding its importance is essential for evaluating the feasibility and sustainability of these projects. The key reasons why CAPEX is vital in geothermal projects are:

1. Initial Investment and Project Feasibility

a. High Upfront Costs: Geothermal projects require significant initial investments, particularly during the exploration and drilling phases. CAPEX covers the cost of land acquisition, drilling exploratory wells, infrastructure development, and setting up geothermal plants.
b. Financial Risk: The high CAPEX associated with geothermal projects introduces substantial financial risks. Investors and developers must secure considerable funding before the project can commence, making it imperative to manage these costs effectively.

2. Impact on Economic Viability
   a. Return on Investment (ROI): The economic viability of geothermal projects heavily depends on the initial CAPEX. Lowering CAPEX can improve the ROI by reducing the payback period and enhancing profitability.
   b. Internal Rate of Return (IRR): As shown in the sensitivity analysis, CAPEX has a significant impact on the IRR of geothermal projects. A high CAPEX can lower the IRR, making the project less attractive to investors and financiers.

3. Operational Efficiency and Cost Management
   a. Operational Costs: While CAPEX primarily focuses on initial costs, it also influences long-term operational efficiency. Investments in high-quality infrastructure and technology can reduce maintenance and operational costs over the project's lifespan.
   b. Cost Overruns: Effective management of CAPEX is crucial to avoid cost overruns, which can derail the project timeline and budget. Accurate estimation and control of CAPEX ensure that the project stays within financial constraints.

4. Financing and Investment Decisions
   a. Attracting Investment: A well-managed CAPEX profile makes geothermal projects more appealing to investors and financial institutions. Transparent and realistic CAPEX estimates build confidence among stakeholders and facilitate funding.
   b. Financing Terms: The ability to control and justify CAPEX can influence the terms and conditions of financing. Lower CAPEX may lead to more favorable loan terms and interest rates, reducing the financial burden on the project.

5. Regulatory and Environmental Considerations
   a. Compliance and Permitting: CAPEX includes costs related to regulatory compliance and environmental permitting. Ensuring that these aspects are adequately funded is essential for project approval and sustainability.
   b. Sustainability Investments: Allocating CAPEX towards sustainable practices and technologies can enhance the environmental profile of geothermal projects, aligning them with national and international sustainability goals.

3.1 CAPEX Components

Understanding the CAPEX component in geothermal projects is critical for effective financial planning, risk management, securing investment, and ensuring long-term operational efficiency. It enables stakeholders to make informed decisions, optimize costs, and enhance the overall feasibility and sustainability of geothermal energy projects. By comprehensively analyzing CAPEX, project developers can better navigate the complexities of geothermal project development and contribute to the successful expansion of geothermal energy capacity. The typical CAPEX component in a geothermal project is show in Table 6. In the following chapter, this study will present a project economic simulation with different CAPEX levels during the exploration phase. The first case involves slimhole drilling with lower CAPEX, compared to the second case, which uses bighole drilling with higher CAPEX.

Table 6: The list of CAPEX component in a geothermal project..

CAPEX component	Remarks
Preliminary survey	The cost related to 3G Survey, permittance, and desk study
Exploration	Cost related to the permittance, ESIA study, land acquisition, infrastructure work, and exploration well to confirm the presence of geothermal resource.
Appraisal	Cost related to the additional permittance, land acquisition, infrastructure work, and appraisal well to provide required steam under well-head for FID purpose. The appraisal cost in project November is higher than exploration cost since this stage has more well to drill.
Development	Cost related to the additional permittance, land acquisition, infrastructure work, drilling, and EPC SAGS-power plant.

CAPEX component	Remarks
De-risking and GREM	Cost related to the payment of GREM or other de-risking facility (i.e. commitment fee, interest, and success premium).
Finance cost	Cost related to financing activity for development phase (i.e. interest during construction, and commitment fee)
Reinvestment	Cost related to the make-up well drilling activities after COD.

3.2 Impact of Various Cost Components on the Internal Rate of Return (IRR) of Geothermal Projects

Understanding which cost components most impact Internal Rate of Return (IRR) and the role of IRR in geothermal projects is essential for effective financial planning, risk management, and strategic decision-making. By focusing on the most influential cost drivers, stakeholders can enhance project viability, attract investment, and ensure sustainable development. The insights gained from analyzing the impact of exploration costs on IRR are critical for optimizing the economic feasibility of geothermal projects in Indonesia, ultimately contributing to the country's energy security and sustainable development goals.

The IRR is a crucial metric for assessing the profitability and efficiency of geothermal projects. A higher IRR indicates a more financially attractive project, making it easier to attract investors and secure funding. IRR serves as a benchmark for comparing geothermal projects with alternative investments, helping stakeholders choose projects with the best potential returns. It boosts investor confidence by reflecting the project's potential for adequate returns, which is essential for securing both private and institutional investments. Financial institutions often use IRR as a criterion for funding approval, with strong IRRs leading to more financial support.

IRR also provides a quantitative measure of project performance over its lifecycle, aiding in evaluating whether the project meets financial goals. It assists in long-term planning and forecasting, guiding future project developments and expansions. Furthermore, IRR helps assess financial risk, with lower IRRs indicating higher financial risks and the need for risk mitigation strategies. By setting investment thresholds based on IRR, projects can ensure that only financially viable projects are pursued, optimizing resource use and enhancing project success.

Figure 3 provided offers a sensitivity analysis that highlights the impact of various cost components on the Internal Rate of Return (IRR) of geothermal projects. The primary takeaway from this analysis is the significant influence of Capital Expenditure (CAPEX) on the economic viability of geothermal projects. This insight is crucial for understanding the broader context of exploration costs in the geothermal sector.

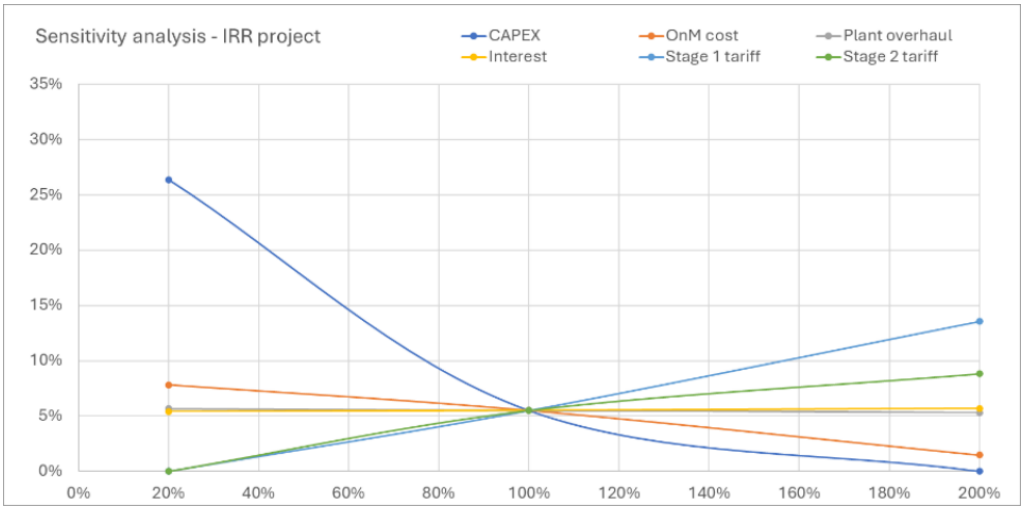

Figure 3: The Significancy of Capital expenditure (CAPEX) to the Geothermal Project Economics (GRG-Geoenergis, 2024).

Additionally, Figure 4 presents a sensitivity analysis of a geothermal project to identify the most influential parameters on the project's return. This analysis is crucial as additional project efforts are required to ensure a fair return on equity. The NPV-IRR sensitivity analysis includes parameters such as CAPEX, OPEX, and tariffs.

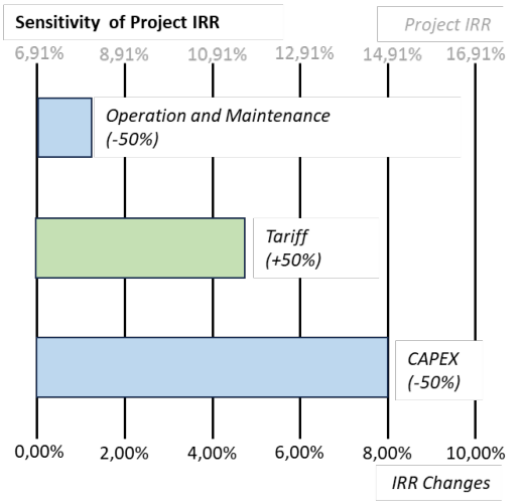

Figure 4: The Tornado Chart of Sensitivity analysis of Project IRR (GRG-Geoenergis, 2024).

Key Observations from Figure 3 and Figure 4 are:

1. Dominance of CAPEX:
    a. CAPEX emerges as the most influential factor affecting the IRR of geothermal projects. The sensitivity analysis demonstrates that changes in CAPEX have a more pronounced impact on the IRR compared to other cost components.
    b. The IRR's sensitivity to CAPEX underscores the critical nature of managing capital costs effectively to ensure project feasibility. High CAPEX can severely undermine the financial attractiveness of geothermal projects, leading to potential financial inefficiencies.
2. Comparison with Other Cost Components:
    a. While Operation and Maintenance (OnM) costs, plant overhaul expenses, and interest rates also influence the IRR, their impact is relatively less significant compared to CAPEX.
    b. The analysis indicates that changes in tariffs (both Stage 1 and Stage 2) also affect the IRR, particularly the Stage 2 tariff, which shows a substantial impact. However, CAPEX remains the dominant factor.
3. Implications for Exploration Costs:
    a. Exploration costs, as a component of overall CAPEX, play a crucial role in determining the financial feasibility of geothermal projects. The variability in exploration cost management practices can lead to significant discrepancies in CAPEX, thereby affecting the IRR.
    b. The high sensitivity of IRR to CAPEX highlights the need for standardized and efficient exploration cost management practices among stakeholders, including government agencies, SOEs, private developers, and new entrants.

4. CASE ANALYSIS: ALPHA GEOTHERMAL PROJECT

At the beginning of this study, the authors planned to conduct a financial simulation using data from actual exploration projects in Indonesia, selecting two sample projects with exploration costs under 50 MUSD and two sample projects with costs exceeding 50 MUSD. Unfortunately, due to concerns over data confidentiality and the fact that the sampled exploration projects were still ongoing, the authors decided to use hypothetical data so that the study could proceed and be published.

4.1 Assumptions

“Alpha Geothermal” Project is hypothetical 55MW net geothermal power plant that is in Java area. The 55MW capacity is selected based on the most projected geothermal power plant in RUPTL 2021-2030 (Figure 5). The Java area is projected to have the highest additional installed geothermal power plant capacity (Figure 6). Alpha project has 20.000 Ha working area. Figure 5 shows the distribution on expected power plant capacity on RUPTL 2020-2030, while Figure 6 emphasize Java area as highest region of planned geothermal power plant.

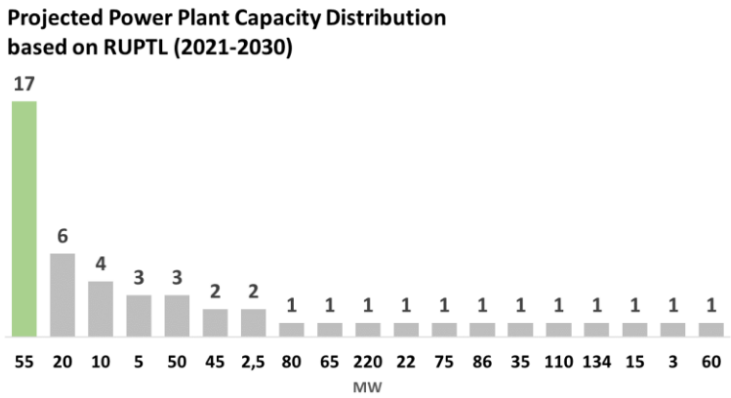

Figure 5: The Distribution of Projected Geothermal Power Plant Capacity per Number of Units.

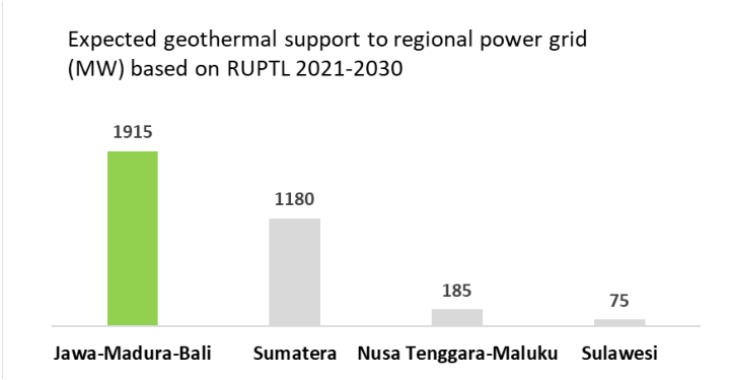

Figure 6: The Distribution of Expected Geothermal Power Support for Each Region.

This "Alpha Geothermal" project addresses the conditions necessary to determine the appropriate drilling strategy from a financial perspective. Four scenarios (Table 7 and Table 8) were simulated in this study, comparing two teams using different approaches. The slimhole scenario assumes a team with a mindset focused on phased and cautious development, while the bighole scenario assumes a team aiming for rapid development.

Table 7 outlines the assumptions used in each scenario, with all four cases progressing through three project phases: exploration, appraisal, and development. The cost and success rate assumptions were made by the authors, based on various references (IGA, 2014; IRENA, 2015; IFC, 2013; Adityatama et al., 2020; Purba et al., 2021b) and interviews with several geothermal experts in Indonesia conducted during this study.

Table 7: Assumptions explanation of each scenario assessed in this study.

Cases / Scenarios	Exploration	Appraisal	Development
Slimhole	A total of five slimhole wells were drilled, considering the relatively low cost of slimhole drilling (USD 2M per well). The costs already account for drilling infrastructure and mobilization-demobilization expenses. The objective was to cover a wider tested area to provide the exploration team with more data for resource assessment and planning for the next drilling phase. At this stage, the drilling success ratio is assumed to be only 40%, meaning that out of the five wells drilled, only 2	After successfully confirming the resource with two slimhole wells out of the 5 (five) drilled, the team had sufficient data to proceed with field development using bighole wells. However, recognizing the remaining risks, the team decided to adopt a phased strategy for the 10 wells to be drilled. They would first drill five wells, evaluate the results, and proceed with the next five wells if deemed feasible. The drilling success rate increased to 70%, as the five initial drilling points could serve as valuable references. As a	With the availability of data from five slimhole wells and ten bighole wells, where a total of 9 (nine) wells provided information confirming the presence of the resource and its characteristics, the success rate at this stage can be assumed to be 80%. This means that to achieve the remaining 30 MW, only 8 (eight) more wells are needed, assuming six of them will successfully produce 5 MW per well. The total capacity achieved would be 65 MW, which includes a buffer for the utilization of 55 MW.

Cases / Scenarios	Exploration	Appraisal	Development
	(two) successfully confirmed the presence of the resource.	result, there will be 7 (seven) wells that can serve as production wells, providing a total of 35 MW at the wellhead.	
Slimhole Overrun	The same assumptions as the slimhole case above apply; however, in this scenario, one slimhole well encountered operational issues, resulting in a cost overrun of up toUSD 3M.	The same assumptions as the slimhole case above apply.	The same assumptions as the slimhole case above apply. The difference is that due to the cost overrun during the explorationphase, there is an additional cost of USD 1M compared to the previous slimhole scenario.
Bighole	In this scenario, the exploration team chose to use bighole drilling, with a total of three wells costing USD 9M per well, including mobilization-demobilization and infrastructure. The team opted for bighole drilling as they were more familiar with full-size wells and wanted the option for directional drilling and sidetracking when needed. The drilling success ratio is 40%, meaning that out of the three wells drilled, only one will confirm the presence of the resource. The team also hoped that if a well was successful, it could be directly used as a production well, with the assumption that one successful well could yield 5MW per well.	Since only one well in the exploration phase successfully confirmed the presence of a subsurface resource, the risk during the appraisal phase remains high, with the drilling success ratio only increasing to 60%. With this success ratio, only six wells out of the ten drilled will successfully produce 5 MW per well, providing 30 MW at the wellhead, which totals 35 MW when combined with the 5 MW already obtained during the exploration phase. In this scenario, it is assumed that the team opted to drill all 10 bighole wells without conducting an evaluation after the first five wells.	Since there is data from only 13 wells, and only seven of those wells provided information on the presence and characteristics of the resource, the success rate at this stage increases to only 75%. This means that nine additional wells are needed to obtain six wells with a capacity of 5 MW per well, equivalent to an additional 30 MW at the wellhead. This would result in a total of 65 MW when combined with the capacity achieved during the exploration and appraisal phases.
Bighole Overrun	The same assumptions as the bighole case above apply; however, in this scenario, one bighole encountered operational issues, resulting in a cost overrun of up to USD 20M. This cost increase is based on actual data, where a stuck pipe incident during bighole drilling can reach up to USD 29M in Indonesia.	The same assumptions as the bighole case above apply.	The same assumptions as the bighole case above apply. The difference is that due to the cost overrun during the exploration phase, there is an additional costof USD 11M compared to the previous bighole scenario.

Table 8 presents the key assumptions outlined in Table 7 that are ready to be incorporated into the financial model for simulation. The figure of 14.5 MUSD per well for failed bighole cases in the exploration phase is derived from the average of two failed wells in the bighole case. The first well experienced an overrun, reaching up to 20 MUSD, while the second well, although it failed to confirm the resource, remained within the 9 MUSD/well budget. This gives a total of 29 MUSD, which, when divided between the two wells, results in an average of 14.5 MUSD per well.

Each case will aim for a target of 65 MW gross total well capacity, considering a buffer of 10-30% from the net target of 55 MW. A middle value is assumed, with approximately 10 MW considered sufficient as a buffer to account for various issues that may arise during production.

4.2 The "Walkaway" Cost

The walkaway cost in geothermal project represents the cumulative financial loss incurred if the project is terminated before reaching the production stage, typically due to poor resource quality, technical challenges or significant unresolved issues during project. Analyzing walkaway costs is crucial for assessing the financial viability and risk exposure of geothermal projects, particularly during the early stages of exploration and appraisal that financed by equity. The understanding of walkaway cost is important to provide crystal view of the worst-case financial scenario. It serves as indicator to take necessary action to safeguard the investment through appropriate project strategy and risk mitigation.

Exploration teams might overlook walkaway costs in project planning due to a focus on success, where failure scenarios are seen as unlikely. Pressure to meet tight deadlines and financial targets can lead to skipping detailed risk assessments. Estimating walkaway costs is complex, and many decision-makers underestimate or ignore these costs, seeing them as low-probability risks. Additionally, financial planning tends to prioritize upfront costs and potential returns, leaving walkaway costs underemphasized.

Table 8: The key assumptions on the exploration drilling aspect for financial model input.

	Slimhole	Slimhole overrun	Big hole	Big Hole overrun
Exploration Phase				
Exploration success ratio	40%			
-Exploration drilled well				
--Slimhole	5 wells	5 well	-	-
--Big hole	-	-	3 wells	3 wells
Well cost				
-- Success slimhole	2 MUSD/well		-	-
-- Failed slimhole	2 MUSD/well	3 MUSD/well	-	-
-- Success big hole			9 MUSD/well	
-- Failed big hole			9 MUSD/well	14.5 MUSD/well
Appraisal Phase				
-Appraisal success ratio	70%		60%	
-Appraisal drilled well				
-- Big hole	5 +5 wells	5 +5 wells	10 wells	10 wells
Well cost				
-- Success big hole	9 MUSD/ Well			
-- Failed big hole	9 MUSD/ Well			
Development Phase				
-Development success ratio	80%		75%	
-Development well				
-- Big hole	8 wells	8 wells	9 wells	9 wells
Well cost				
-- Success big hole	9 MUSD/ Well			
-- Failed big hole	9 MUSD/ Well			

The authors have obtained data from at least two geothermal projects in Indonesia that are still in the exploration phase. However, this data is confidential and cannot be published in this paper. Both projects have spent over 50 MUSD on exploration costs without reaching any significant conclusions about the resources in the prospective areas. This puts the investors in a difficult position, as a substantial amount of money has already been spent, making it hard to abandon the project due to the large sunk costs. However, they also lack sufficient data to move forward, meaning further expensive drilling activities are still required. This situation arose because the decision-makers in charge of the exploration projects did not consider walkaway costs in their planning.

In the simulation of "Alpha Geothermal" project, the slimhole case demonstrates lower walkaway cost compared to the bighole scenario. If developer decides to exit the project after the exploration phase, the financial loss in the slimhole scenario is estimated at 10-11 million USD (Figure 7), whereas the big hole scenario could result in a loss of up to 27-38 million USD (Figure 8). Utilizing slimholes provides a cost-effective method for resource confirmation, as it allows for more efficient allocation of capital during the high-risk exploration phase. This approach enables developers to assess multiple areas for better evaluation and decision making with similar investment levels required for single bighole well, which typically only tests one location.

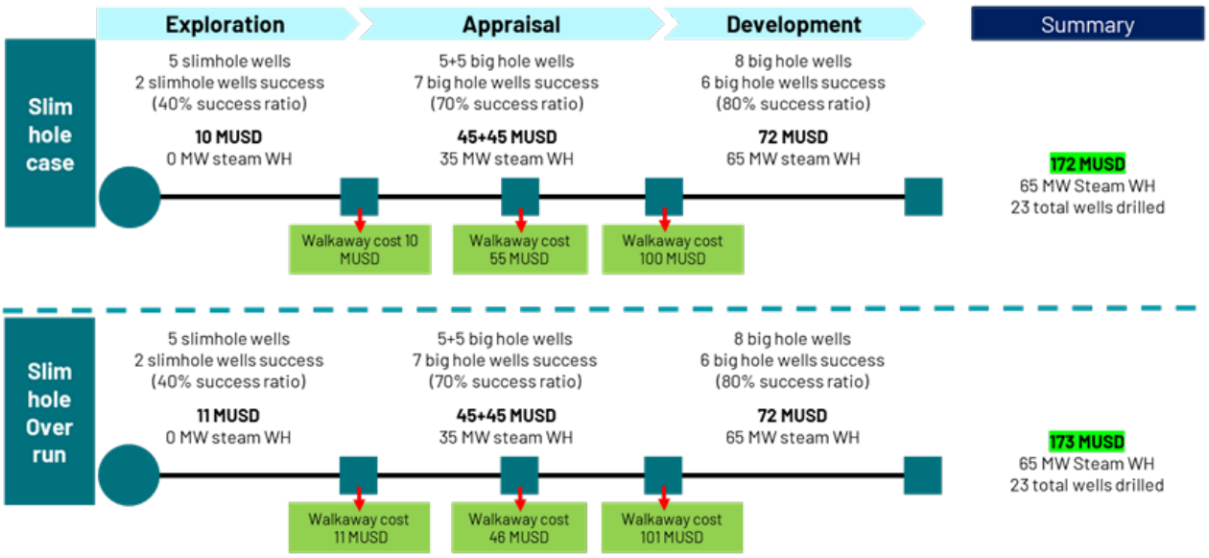

Figure 7: Walkaway Illustrations of Slimhole Cases: Normal and Overrun.

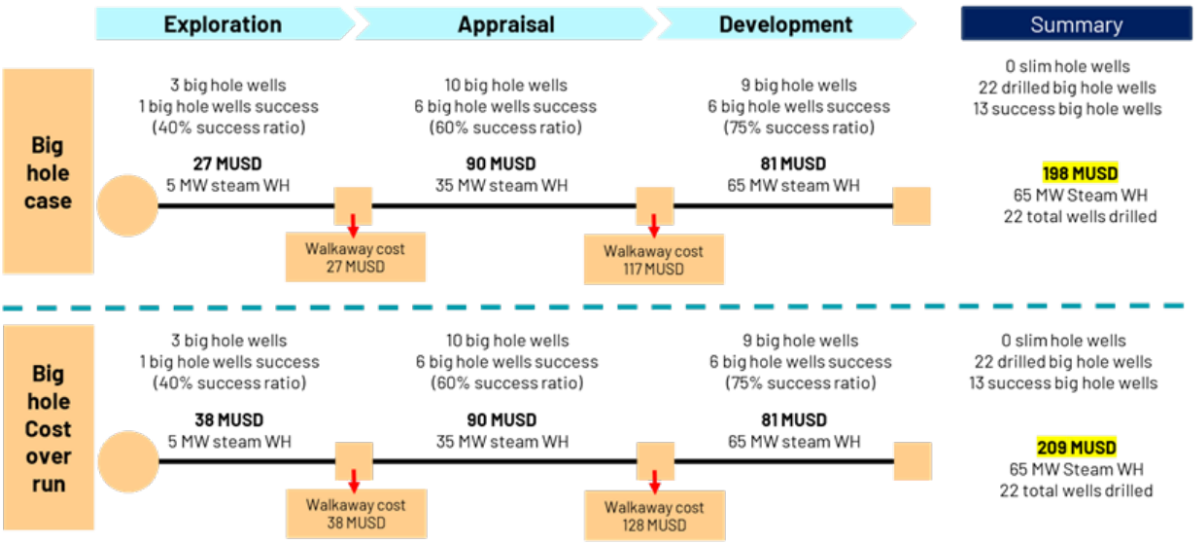

Figure 8: Walkaway Illustrations of Bighole Cases: Normal and Overrun.

4.3 Net Cashflow and Equity Return

Figure 9 shows the cash flow graph for the hypothetical 55 MW Alpha Project comparing the financial trajectories of big hole and slim hole drilling scenarios. During the early exploration and appraisal stages, which are typically financed entirely by equity with no external debt involvement, the slimhole scenario shows a clear financial advantage. The lower initial capital required for slim hole drilling results in smaller negative cash flow, reducing the burden on equity funding.

The bighole scenario, with its substantial equity cash requirements, poses a greater financial risk during these early stages. In contrast, the slim hole approach not only mitigates this risk but also provides greater financial flexibility by preserving equity capital. This reduced financial exposure allows for a more phased investment approach, enabling the developer to better manage uncertainties and adapt to changing project dynamics without jeopardizing the overall financial performance of the project.

Lowering CAPEX during exploration and appraisal stages improves net cash flow and boosts equity returns. With reduced upfront costs, especially through slimhole drilling, the project requires less capital, leading to smaller cash flow deficits and faster equity break even point. This strengthens the project's financial position, making future financing easier and reducing reliance on additional equity or costly debt. Additionally, lower CAPEX enhances the internal rate of return (IRR), as lower investment yields the same future revenue, resulting in higher overall equity returns and making the project more financially attractive.

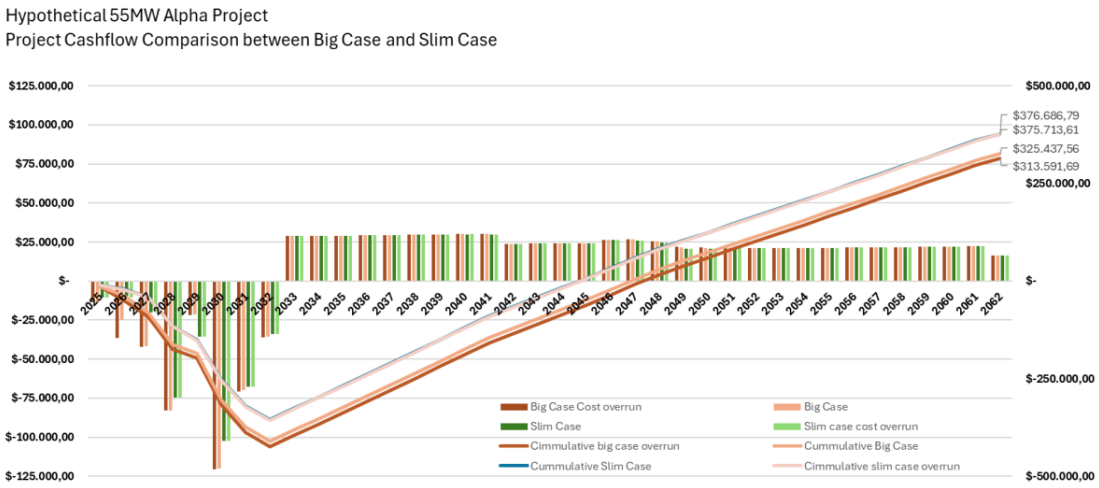

Figure 9: The Cashflow Graph for The Hypothetical 55 MW Alpha Project Comparing the Financial Trajectories ff Bighole and Slimhole Drilling Scenarios.

Table 9 illustrates the Internal Rate of Return (IRR) for equity under both base and cost overrun conditions for slim hole and big hole drilling scenarios. In the base condition, the slimhole scenario achieves an IRR of 6.48%, compared to just 4.17% for the big hole case. This suggests that slimhole drilling provides more favorable return on equity due to its lower upfront costs and reduced financial exposure during the high-risk exploration phase, which is typically funded solely by equity.

When cost overruns occur, the IRR for the slimhole scenario shows only a slight decline, indicating minimal impact on equity returns despite unforeseen cost increases. In contrast, the bighole scenario experiences a significant decline in IRR, highlighting its risk to cost escalations during the exploration stage. This is particularly critical because any failure in the bighole scenario can severely impact the overall project's financial viability, placing a substantial burden on equity investors.

Table 9: Comparison of IRR Equity between slim case and big case.

IRR Equity	Base condition	Cost overrun condition	Changes
Slim case	6.48%	6.44%	-0.04%
Big case	4.17%	3.52%	-0.65%

4.4. Discussion on Slimhole vs Bighole Based on the Simulation Result

The financial simulations in sub-sections 4.2 and 4.3 show that slimhole drilling offers several advantages over bighole drilling, especially if a significant cost overrun occurs during bighole operations. Numerous papers have already discussed the technical aspects of why slimhole drilling is much more cost-effective and worth considering for exploration in Indonesia (GRG-Geoenergis, 2024; Purba, 2018; Purba et al., 2021a; Purba et al., 2021b; Apriani et al., 2018; Adityatama et al., 2020; Adityatama et al., 2021; Purba et al., 2019; Sumardi, 2022a; Sumardi 2022b; Wiharlan, 2021). In this sub-section, the authors will briefly discuss the comparison between slimhole and bighole drilling in terms of resource assessment during the exploration phase.

4.4.1 Wider coverage of testing area with lower cost using slimhole

Slimhole drilling offers significant advantages in geothermal exploration, particularly in terms of cost efficiency and maximizing subsurface data collection. With unit costs ranging from approximately 1.5 to 3 MUSD per well, slimhole wells are considerably more affordable than bighole wells, which typically cost between 7 and 10 MUSD per well. This substantial cost difference allows for a higher number of wells to be drilled with the same budget. For example, the cost of drilling one bighole well can be used to drill between three to five slimhole wells. By drilling more wells, exploration teams can cover a larger geographical area, providing a more comprehensive understanding of the subsurface.

The increased number of wells drilled through slimhole techniques significantly enhances the quality and quantity of data collected. Each additional well provides crucial information about the geothermal reservoir's characteristics, such as fluid flow, pressure, and temperature. This data is essential for reservoir numerical modeling, allowing for more accurate predictions of resource potential and reducing the uncertainties that typically accompany geothermal exploration. As a result, slimhole drilling not only offers cost savings but also improves

the overall reliability of resource assessments, helping to optimize the subsequent development phases and reduce financial risks.

4.4.2 Overall project economics enhancement

Slimhole drilling not only reduces costs during the exploration phase but also significantly increases the likelihood of success in the appraisal and development phases. By testing more areas with slimhole wells, exploration teams can gather a much deeper understanding of the subsurface characteristics, such as fluid distribution, temperature gradients, and reservoir boundaries. This improved understanding helps to identify the most promising drilling locations, leading to a higher success rate when transitioning to the appraisal and development stages. As a result, the overall project risks are reduced, increasing the chances of securing productive wells in subsequent phases.

Additionally, the higher success rates during appraisal and development due to slimhole data reduce the need for unnecessary drilling activities, which directly translates to lower total drilling costs. This cost reduction improves the economic feasibility of the project, making it more attractive to investors and lenders. The time gained by using slimholes for early-stage exploration also allows project developers to thoroughly analyze the data, prepare more accurate project proposals, and engage potential investors or lenders with greater confidence, further boosting the project's financial prospects.

4.4.3 Minimizing Walkaway Costs

One of the significant advantages of slimhole drilling in geothermal exploration is its ability to drastically reduce walkaway costs in the event of a failed exploration. In any exploration activity, there is always a risk that the wells drilled may not yield the desired sub-surface geothermal resource, leading to financial losses. With bighole wells, which can cost between 7 and 10 MUSD per well, or 20 MUSD if major incidents happened, the financial impact of a failed well can be substantial, leading to large sunk costs that investors must absorb. In contrast, slimhole wells cost considerably less—typically between 1.5 and 3 MUSD per well—so the financial impact of a failed exploration is much lower. This reduction in walkaway costs makes slimhole drilling a more attractive option, especially in high-risk areas where the likelihood of failure is uncertain.

For investors, reducing the financial risk associated with exploration is a key factor in decision-making. Slimhole drilling provides a safety net by lowering the potential losses in case a well does not produce viable geothermal resources. This makes it easier for investors to commit to exploration projects, as their financial exposure is minimized.

4.4.4 The risk of bighole overrun cost

In geothermal drilling, particularly with bighole wells, the risk of cost overruns due to major incidents like stuck pipe is a significant concern. Data from Indonesia shows that such incidents can increase costs by as much as 29 MUSD (Table 10). Stuck pipe occurs when the drill string becomes stuck and trapped in the wellbore, often due to challenging subsurface conditions. This issue is not uncommon, especially in exploration phases, where the subsurface is largely unknown. Even during the development phase, stuck pipe remains a frequent problem, as Indonesia's volcanic systems are highly heterogeneous, making it difficult to create accurate geoscientific predictions. This unpredictability adds to the operational risks and often leads to costly delays and additional drilling efforts.

Table 10: Actual drilling cost from 13 wells of bighole drilling in Indonesia (GRG-Geoenergis, 2024).

No.	Well Name	Project Location	Well Depth (mMD)	Total Drilling Cost (USD)	Drilling Cost per meter (USD/m)	Well Status
1.	Well 1	Sumatera	2,160	$29,408,487	$13,615	Non-productive
2.	Well 2	Sumatera	1,654	$28,441,465	$17,196	Non-productive
3.	Well 3	Sumatera	2,941	$24,110,166	$8,198	Productive
4.	Well 4	East Java	2,770	$22,904,286	$8,269	Productive
5.	Well 5	Sumatera	3,014	$21,352,215	$7,084	Productive
6.	Well 6	Sumatera	2,272	$19,824,782	$8,725	Non-productive
7.	Well 7	Sumatera	3,006	$17,559,075	$5,841	Productive
8.	Well 8	Sumatera	1,503	$17,335,170	$11,534	Non-productive
9.	Well 9	Sumatera	1,253	$17,323,032	$13,825	Non-productive
10.	Well 10	Sumatera	2,133	$15,988,860	$7,494	Non-productive
11.	Well 11	Sumatera	1,829	$15,938,855	$8,716	Non-productive
12.	Well 12	Sumatera	1,668	$15,605,100	$9,356	Productive
13.	Well 13	Sumatera	2,500	$15,563,587	$6,225	Non-productive

The challenge of avoiding drilling surprises is heightened by the fact that exploration drilling is typically planned with very limited subsurface data. This lack of comprehensive information increases the likelihood of encountering unforeseen subsurface hazards, such as unstable formations or high-pressure zones, which can result in stuck pipe or other major incidents. Additionally, the cost implications of such incidents are exacerbated by the high daily rental rates of rigs used for drilling slimhole wells, which generally require 1,000 to 2,000 horsepower, depending on the well design, drilling trajectory, and rig availability. When stuck pipe or other significant issues occur, the rig rental costs can skyrocket, as the downtime needed to resolve the problem directly translates into higher expenses. With daily rig rental costs being substantial, a delay of just a few days can quickly inflate overall project costs, adding to the financial risks already inherent in geothermal exploration.

These risks make cost management critical in geothermal projects, particularly during the exploration phase. While slimhole drilling offers a lower-cost alternative to bighole wells, the potential for cost overruns remains high due to Indonesia's complex geological conditions. Therefore, thorough planning, real-time monitoring, and flexible mitigation strategies are essential to minimize the financial impact of such incidents and ensure that geothermal exploration remains economically viable.

5. MANAGING EXPLORATION COST

5.1 High Level Strategy in Managing Exploration Cost

After reviewing the analysis in Figure 3 and Figure 4, it is evident that managing exploration costs is critical for maintaining a favourable IRR and ensuring the economic feasibility of geothermal projects. Based on the sensitivity analysis, these are several key considerations to optimize exploration expenditures and enhance project feasibility:

1. *Implement Standardized Cost Management Practices*: Develop and enforce standardized practices for managing exploration costs across different stakeholders. This can help reduce financial inefficiencies and ensure more predictable CAPEX outcomes.
2. *Adopt Best Practices from Successful Case Studies*: Analyse and adopt cost management strategies from successful geothermal projects that have managed to control exploration costs effectively. Sharing these best practices can help other projects achieve similar efficiencies.
3. *Policy Support for Cost Reduction*: Advocate for supportive policies that facilitate cost reductions in exploration. This includes providing financial incentives, streamlining regulatory processes, and promoting technological innovations that can lower exploration costs.
4. *Focus on Cost-Effective Exploration Techniques*: Invest in research and development of cost-effective exploration techniques. Utilizing advanced geophysical surveys, drilling technologies, and data analytics can help reduce the overall cost burden of exploration.

5.2 Role in Advanced Reservoir Numerical Modelling to Optimize Exploration Strategy

A study by O'Sullivan et al. (2024) demonstrated that reservoir numerical modelling has played a critical role in assessing the potential of six undeveloped geothermal fields in Indonesia: Ciremai, Kepahiang, Kotamobagu, Maritaing, Massepe, and Papandayan. These fields present complex geological conditions, and traditional exploration methods would have faced significant challenges in providing accurate resource estimates due to the uncertainties associated with subsurface characteristics.

Table 11: Summary of reservoir numerical modeling on six undeveloped geothermal fields in Indonesia (O'Sullivan et al., 2024).

Field	Geological Features	Modeling Outcome	Main Challenges	Potential Power Output Estimate	Numerical Modeling Remarks
Ciremai	Volcanic-type system, deep water table, complex stratigraphy	Identified need for highly deviated wells due to deep water table	Deep water table affecting well discharge pressure	55.1 MWe	Developed a highly deviated well scenario due to deep water table, improving well placement strategy.
Kepahiang	Thick clay cap, volcanic nature, fault-controlled fluid movement	More conservative estimate of potential due to deep reservoir	Thick clay cap complicating access to geothermal resource	63.1 MWe	Refined the resource potential estimate with a focus on the deep reservoir beneath the clay cap.

Field	Geological Features	Modeling Outcome	Main Challenges	Potential Power Output Estimate	Numerical Modeling Remarks
		beneath clay cap			
Kotamobagu	Complex geological setting with multiple volcanic formations, uncertain reservoir size	Refined target reservoir size, smaller than initial interpretations	Uncertainty in target reservoir size based on MT data	270 MWe	Provided a more accurate target reservoir size, addressing the uncertainties from initial geophysical surveys.
Maritaing	Fault-controlled fluid system with volcanic and sedimentary formations	3D geological model improved understanding of fault-controlled fluid movement	Complex interaction of volcanic and sedimentary formations	22.9 MWe	Created a 3D geological model to clarify fault-controlled fluid movement, enhancing reservoir understanding.
Massepe	Upflow zone identified through resistivity anomalies, fault-controlled	Resistivity anomalies mapped the upflow zone, optimizing well placement	Identifying optimal drilling locations in upflow zone	43.4 MWe	Mapped resistivity anomalies and identified upflow zones for optimal well placement.
Papandayan	Volcanic-type system with complex fault structures and a clay cap dome	Identified feasible drilling locations and clarified the impact of fault structures	Navigating fault systems and clay cap to determine drilling feasibility	28.4 MWe	Assessed fault structures and the clay cap to identify feasible drilling locations and refine power output estimates.

In all six cases, numerical modelling provided more realistic resource assessments, helping to identify the challenges and opportunities unique to each geothermal field. By integrating real-world data and simulating production scenarios, these models offered insights that traditional methods could not, ultimately aiding in the decision-making process for developing Indonesia's geothermal resources efficiently.

In short, the study (O'Sullivan et al., 2014) presents six case studies showcasing a new framework for assessing the resource potential of geothermal systems. The framework utilizes early-stage exploration data to calibrate numerical reservoir models and estimate the potential power output of geothermal systems. This approach offers a more realistic estimate of geothermal resource potential compared to traditional methods, such as stored heat calculations, as it better accounts for the complex dynamics within the reservoir that influence energy extraction. By applying advanced numerical models, researchers were able to generate more reliable data on each field's potential power output, helping stakeholders make informed decisions regarding project feasibility.

5.3 Cost Reduction Options in Drilling

Implementing initiatives to reduce geothermal development costs in Indonesia is essential for enhancing the feasibility and efficiency of geothermal projects. Based on an evaluation of development cost data from three fields in Indonesia between 2019 and 2024 (GRG-Geoenergis, 2024), drilling is one of the components have the highest costs among the other cost components. Therefore, initiatives to reduce the overall development cost through optimization of drilling costs may be critical.

Employing initiatives to reduce geothermal drilling costs in Indonesia is crucial for enhancing the overall feasibility and efficiency of geothermal projects. Based on an evaluation of drilling cost data, drilling issues related to stuck pipes and well control (blowouts) can significantly inflate costs, sometimes exceeding 10 million USD per well. Therefore, initiatives to reduce the likelihood of such problems with stuck pipes and well control are critical. By addressing these issues, drilling costs can be kept within a reasonable threshold, as determined by expert interviews. In general, the authors identify two opportunities for project owners to optimize drilling costs, which are in the planning phase and operation phase, as outlined in Table 12.

To clarify the points outlined in Table 12 and provide specific examples, a study by GRG-Geoenergis (2024) has identified a range of initiatives for reducing geothermal drilling costs, drawing from various efforts by geothermal

developers both in Indonesia and globally. A detailed explanation of these initiatives and strategies is provided in the GRG-Geoenergis (2024) report, while a brief illustration of the initiatives is presented in in Figure 10.

5.4 Geothermal De-risking Scheme

Several approaches could also play a role in optimizing development costs, including geothermal de-risking scheme, soft loan application, and the optimization of derivative geothermal products. One of the initiatives by the Indonesian government to promote geothermal exploration projects is the creation of exploration financing schemes that include de-risking features, or in some cases, the government directly taking over exploration activities in a prospective area. A geothermal exploration risk mitigation scheme involves a set of strategies and measures aimed at reducing the financial risks associated with geothermal resource exploration. Common exploration methods encompass various techniques, such as conducting surface studies, drilling test wells, and constructing a conceptual model of the geothermal system. Typically, geothermal developers fund these activities using their company's equity (Siahaan, Septiani, & Purba, 2023).

Financial institutions often hesitate to finance geothermal exploration projects due to their lack of familiarity with such ventures and the inherent risks linked to geothermal resource viability. To address this challenge, government bodies and donor organizations have established programs to mitigate or significantly reduce the financial risks associated with geothermal exploration projects. These risk reduction programs may encompass government-led exploration initiatives, loan guarantees, grants, cooperative agreements, drilling failure insurance, and cost-sharing arrangements. Currently, there are several risk mitigation schemes for geothermal exploration projects. Table 13 provides a summary of the available facilities aimed at de-risking geothermal exploration in Indonesia.

Table 12: Areas of opportunities to optimize exploration drilling cost.

Phase	Typical cost-optimization areas / opportunities	Implementation Challenges
Planning phase	1. **Key personnel recruitment**: Prioritize hiring highly competent personnel over those with less experience to ensure the ability to design a cost-effective drilling plan. 2. **Well type selection and well design**: Conduct a proper assessment to ensure that the well type and design align with the exploration objectives, meaning they should not be too minimal, but also not excessive ("overkill"). 3. **Rig selection**: Perform rig sizing and market surveys to ensure you acquire a fit-for-purpose rig at the best price, based on current market availability. 4. **Peer-review**: If conducted properly, this process can help project owners identify gaps or potential cost overruns that may not have been adequately mitigated by the exploration drilling planning team. 5. **Collective risk assessment process**: Conduct various meetings and workshops, such as risk assessments, DWOP (Drill-Well-on-Paper), and stuck-pipe prevention campaigns, to ensure that all personnel involved in the exploration drilling project, including consultants and contractors, contribute to the identification and mitigation of drilling risks. This will ultimately help reduce the likelihood of cost overruns during operations due to stuck-pipe incidents, for instance. 6. **Rig, equipment, tool and material inspection**: Ensure that all equipment, tools and materials to be used have been inspected by certified personnel to verify that everything on-site is in proper working condition and ready for use.	1. The geothermal industry in Indonesia is currently facing an expertise gap due to the irregularity of geothermal drilling projects. This makes it difficult to find drilling experts in Indonesia who have both planning experience and a deep understanding of geothermal-specific risks. 2. Rigs used for bighole drilling typically come from the oil and gas industry, while rigs for slimhole drilling are sourced from the mining industry. This means that the geothermal industry is dependent on market conditions in both the oil and gas and mining industries when looking for rigs to use in geothermal exploration projects. 3. The authors found that many Drilling Engineers in Indonesia's geothermal industry are not yet accustomed to or skilled in acting as workshop facilitators. As a result, processes like risk assessments or stuck-pipe prevention campaigns are oftenconducted in a less effective manner.
Operation phase	1. **Key personnel recruitment**: Prioritize hiring highly competent personnel over those with less experience to ensure the ability to execute and supervise operations according to the plan. Additionally, emphasize strong communication skills to ensure the	1. Drilling Supervisors and drilling contractors in Indonesia typically come from the oil and gas industry, meaning geothermal companies often must compete to secure skilled and

Phase	Typical cost-optimization areas / opportunities	Implementation Challenges
	operations and planning teams can collaborate effectively during the execution phase, helping to prevent cost overruns. 2. **Regular monitoring and inspection during operation**: Ensure that critical equipment, tools, and materials are consistently monitored and inspected at regular intervals according to applicable standards, such as inspecting drill strings after drilling one or two wells. 3. **SOP and mitigation plan in place**: Ensuring that the operations team has and fully understands all SOPs and mitigation plans for potential incidents during drilling can lead to smoother operations and reduce the likelihood of cost overruns.	reliable personnel for drilling operations. 2. Operations teams are often hired just as drilling operations are about to begin, leaving them with insufficient time to familiarize themselves with the drilling program. As a result, they may not contribute to improving the planning, which can lead to operations not proceeding according to the initial plan.

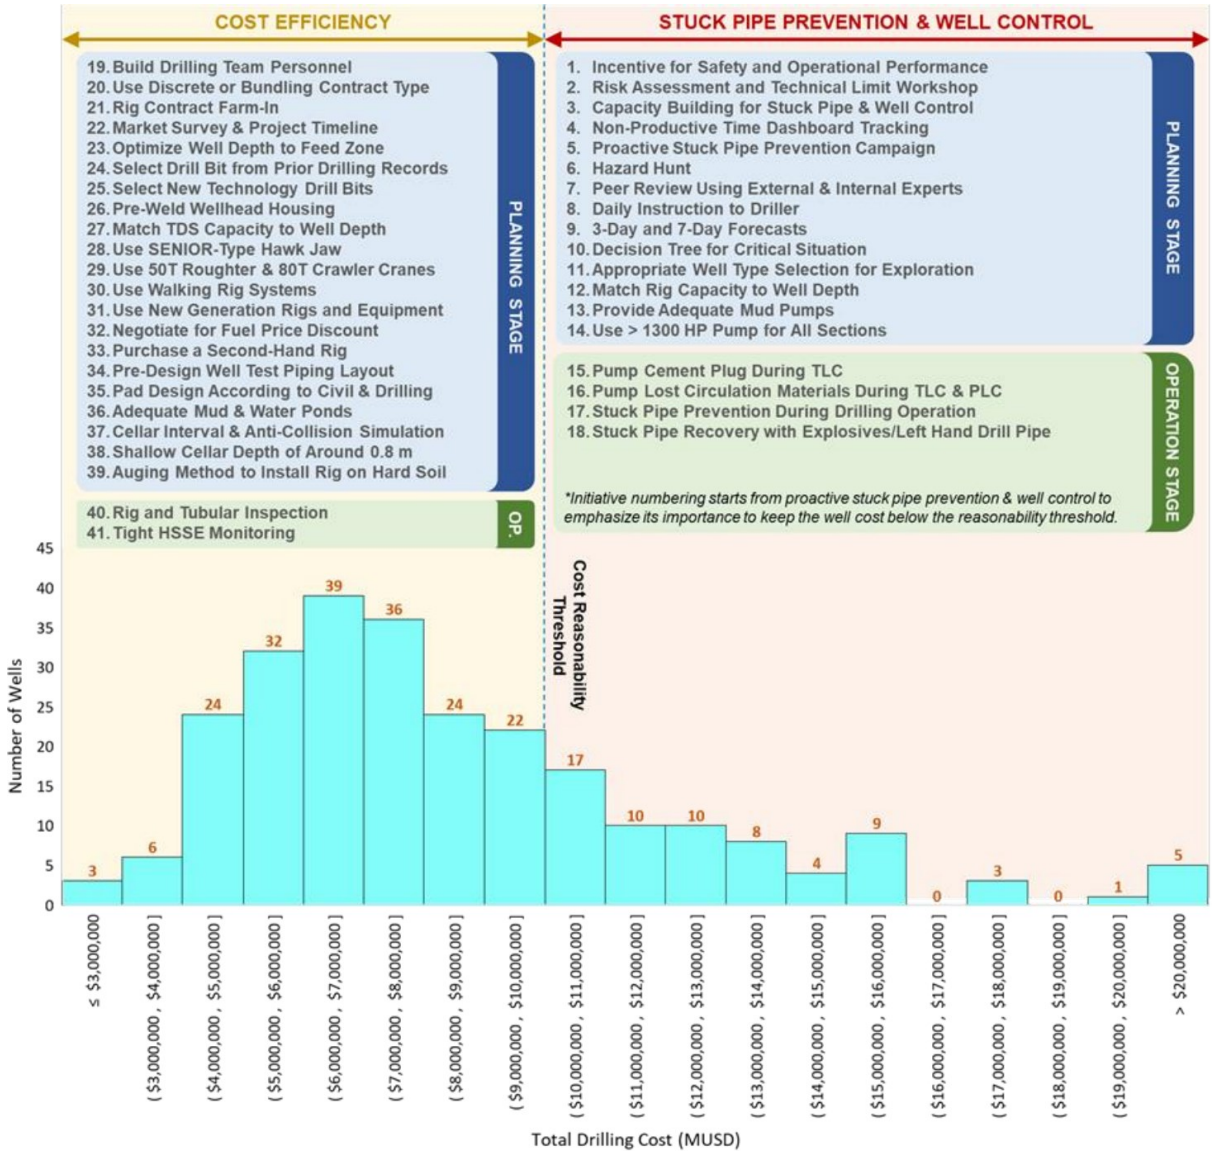

Figure 10: Drilling Cost Reduction Initiatives (GRG-Geoenergis, 2024).

Table 13: Geothermal exploration de-risking facilities in Indonesia (modified from Siahaan, et al., 2023; Apriani et al., 2018).

De-Risking Scheme	Name of Program	Brief Description
Government-led exploration (until exploration drilling)	Geothermal Energy Upstream Development Project (GEUDP)	The GEUDP is a government-sponsored exploration drilling through a collaboration between the Indonesian government and the World Bank. Its primary goal is to develop previously untendered greenfield geothermal areas in remote regions of Indonesia. In this program, the government assumes full responsibility for exploration drilling risks if the resource is either unproven or lacks economic viability.
	Government Drilling Performed by the Geological Agency	The funding for this scheme is sourced from the State Budget (APBN), and the government assumes full responsibility for covering all associated risks. The scope of activities encompasses preliminary surveys, land acquisition, permit procurement, infrastructure construction, drilling operations, well testing, and the updating of pre-feasibility study documents. If the results from the Governments' drilling activities cannot confirm the presence of economically viable geothermal resources, the subsequent phases will be financed through the GEUDP program.
Loan and risk-sharing	Geothermal Resource Risk Mitigation Project (GREM)	The GREM facility consists of two main components, namely: **Component 1:** Referred to as Geothermal Resource Risk Mitigation which introduces a risk-sharing mechanism, wherein developers may be eligible for partial repayment of the facility (up to 50% of the total facility limit) if their exploration efforts prove unsuccessful. **Component 2:** Dedicated to providing technical assistance and enhancing the capacity of SMI and relevant stakeholders.
	State-Owned Enterprise (SOE) Drilling	The SOE drilling program closely resembles the GREM, but it is exclusively funded through the PISP (Geothermal Sector Infrastructure Financing Fund) funds. This facility offers a combination of blended loans and de-risking support.

The various schemes in Table 13, while aimed at sharing the risk between the government and geothermal investors, do not clearly explain how to effectively manage the costs of geothermal exploration projects. This means that the possibility of cost overruns remains high, even when utilizing the available funding facilities. These facilities are designed to share risk, but they lack guidelines for cost-effective exploration project management to ensure the project's feasibility.

6. DISCUSSION AND POTENTIAL WAY FORWARD

This paper dedicates significant discussion to exploration activities, even though the primary focus is on cost aspects. The authors have done this to provide context for readers who may not be familiar with the geothermal industry in Indonesia. The hope is that this paper will trigger further discussions on how to optimize exploration costs in Indonesia. Below is the concluding discussion of this paper.

6.1 Impact of Exploration CAPEX

Geothermal exploration is crucial for Indonesia's energy targets, as most new capacity will come from newly explored areas. Proper exploration management reduces risks and costs, enhancing project feasibility and leading to better resource assessments and investment decisions. Effective exploration practices are vital for government agencies, SOEs, and private developers to ensure economic viability.

Despite challenges, the exploration phase is key to meeting national geothermal targets. The limited development despite Indonesia's vast potential, indicating the need for more exploration efforts. Various entities manage geothermal projects, but disparities in cost management exist due to differences in expertise, resources, and strategies. These inefficiencies lead to overspending and economic challenges, hindering geothermal development.

High exploration costs negatively impact project feasibility, as excessive spending inflates overall costs and reduces economic returns. Aligning cost management practices among stakeholders is essential for maintaining project viability and achieving renewable energy goals. Adopting a development mindset during exploration is

risky and can lead to financial waste. Effective, cost-conscious exploration is crucial to avoid overcommitting resources and ensure long-term project success.

This study emphasizes that CAPEX is a cornerstone of geothermal project development. It affects every aspect of the project, from initial feasibility and financial risk to operational efficiency and investment attractiveness. Effective management of CAPEX is essential for ensuring the economic viability and long-term success of geothermal projects. Stakeholders must prioritize accurate estimation, strategic allocation, and diligent management of CAPEX to optimize project outcomes and contribute to the sustainable development of geothermal energy.

By addressing the critical issue of exploration costs and their impact on CAPEX, stakeholders can enhance the economic viability and attractiveness of geothermal investments in Indonesia. This will ultimately contribute to the country's energy security and sustainable development goals.

Identifying which cost components most significantly impact the Internal Rate of Return (IRR) is vital for effective resource allocation, risk management, strategic decision-making, and financial planning. By understanding the key cost drivers, project managers can allocate resources more effectively, implement better cost control measures, and develop targeted risk mitigation strategies. This knowledge also informs strategic decisions, prioritizing investments that optimize IRR, thereby enhancing the project's financial attractiveness. Additionally, detailed CAPEX analysis can lead to more favourable financing terms, securing better funding conditions.

These insights, derived from the sensitivity analysis, provide a robust foundation for the paper's arguments and recommendations, guiding policymakers, industry stakeholders, and investors towards more effective practices and supportive policy interventions. Furthermore, this paper briefly explores current options identified in the Indonesian geothermal industry that stakeholders might consider for managing their geothermal exploration projects. These options aim to optimize costs and achieve attractive project economics. The authors plan to discuss the details of each option in a separate paper.

6.2 Challenges in Implementing Slimhole Drilling in Geothermal Exploration

Implementing slimhole drilling in geothermal exploration in Indonesia presents several challenges, despite its appeal on financial models. One significant issue is that slimhole drilling is relatively "new" to the current geothermal industry due to the long hiatus in its use. Slimhole drilling was more commonly employed in the 1980s and 1990s, but its utilization largely stopped after the 1998 monetary crisis. It wasn't until 2016 that slimhole drilling re-emerged, leaving a gap of around 20 years without substantial exploration using this method. As a result, much of the current geothermal workforce lacks experience and familiarity with slimhole drilling, making it a less attractive option for many project owners.

Another challenge is the limited availability of reliable slimhole drilling contractors in Indonesia. At the time this study was conducted, only one contractor stood out in the market, but unfortunately, this contractor struggled with poor management. This led to several incomplete drilling projects, leaving many project owners dissatisfied and hesitant to consider slimhole drilling in future endeavours. The lack of trust in slimhole contractors has made it difficult for the method to gain traction, despite its potential cost-saving benefits.

Additionally, the rigs used for slimhole drilling in Indonesia are often sourced from the mining industry. While these rigs can be adapted for geothermal use, the standards and specifications required for geothermal projects are different from those in the mining sector. This necessitates modifications to the rigs, which can add complexity and additional costs to the process. These challenges highlight the need for better contractor management, increased technical expertise, and the development of rigs specifically suited for geothermal exploration if slimhole drilling is to become a more viable and widely accepted method in Indonesia's geothermal industry.

6.3 Policy and Industry Recommendations

To support the development of geothermal projects in Indonesia, both policymakers and industry stakeholders should focus on creating a more favourable environment for cost-efficient exploration. First, the government can enhance its risk-sharing mechanisms to reduce the financial burden on developers, particularly during the high-risk exploration phase. Policies that provide more structured financial support, such as grants or exploration cost guarantees, can incentivize developers to pursue slimhole drilling and other cost-effective techniques without the fear of significant sunk costs.

Secondly, government need to regulate the standardized cost management practices across different stakeholders to minimize financial inefficiencies and ensure predictable capital expenditure (CAPEX) outcomes. Regulations should mandate the adoption of standardized practices for cost estimation, budgeting, and reporting. Establishing regulatory framework that enforces best practices for cost management, including regular audits and financial transparency, will help align project costs with planned budgets and reduce the likelihood of cost

under/overestimate. Additionally, regulatory frameworks should be updated to streamline the permitting process, reducing delays and lowering administrative costs for developers.

From an industry perspective, there is a need for more collaboration among geothermal developers, contractors, and financial institutions to standardize best practices for exploration cost management. Industry-wide initiatives, such as peer reviews and shared databases of exploration results, could help reduce inefficiencies and avoid repeating costly mistakes. Furthermore, investment in workforce training and development is crucial, particularly to address the gap in slimhole drilling expertise. The geothermal stakeholder should put attention in capacity-building programs that focus on specialized geothermal drilling techniques, reservoir modelling, and risk management. These programs can be developed in collaboration with academic institutions and international organizations. This would help to accelerate the learning curve and avoid excessive exploration costs. Finally, by fostering a culture of collaboration and continuous improvement, both policy and industry can contribute to making geothermal exploration in Indonesia more financially viable and sustainable in the long term.

6.4 Future Research Directions

As geothermal exploration continues to evolve in Indonesia, future research should focus on further refining cost-effective exploration techniques, particularly in relation to slimhole drilling. There is a clear need for studies that compare the long-term performance and data reliability of slimhole versus bighole wells beyond the initial exploration phase. Additionally, research should explore innovative ways to integrate advanced reservoir numerical modelling earlier in the exploration process to enhance decision-making and reduce uncertainties. These studies would provide valuable insights for improving well-targeting, minimizing drilling risks, and enhancing resource assessments, thus contributing to a more efficient exploration strategy.

Moreover, future research should examine the potential for new financing mechanisms tailored to support geothermal exploration projects in high-risk areas. Current funding schemes, while helpful, often lack a structured approach to managing cost overruns and walkaway costs. Investigating risk mitigation strategies such as insurance-based solutions, and examining their impact on project feasibility, could significantly reduce financial risks for investors. By advancing research in these areas, the geothermal community can create more resilient and financially viable exploration strategies to help Indonesia achieve its ambitious energy targets.

ABSTRACT

Navigating the challenges of geothermal exploration financing in Indonesia, developers encounter significant obstacles due to the limited availability of financing facilities that address exploration risks. The Government of Indonesia, the World Bank, and PT Sarana Multi Infrastruktur (PT SMI) are crucial in enhancing the sustainable geothermal energy projects by offering exploratory financing and risk mitigation through the Geothermal Resource Risk Mitigation (GREM) program. Developers aiming to utilize this facility must comply with rigorous international financing guidelines, including specific procurement guidelines for public developers.

This paper reviews lender documentation and publications to elucidate the GREM procurement guidelines and the advantages that compliance brings to developers. Additionally, it addresses the complexities and administrative challenges developers encounter in adhering to these guidelines. The author proposes several measures to streamline the procurement process, enhancing collaboration between lenders and borrowers.

In conclusion, this paper delineates a comprehensive strategy for geothermal developers to effectively navigate lender procurement guidelines. By clarifying these processes and suggesting methods to alleviate administrative burdens, it aims to enhance project viability and promote the wider adoption of geothermal energy exploration in Indonesia.

1. INTRODUCTION

Indonesia's ambitious plan to significantly expand its geothermal power plant installed capacity is illustrated by the country's target of reaching 5,799 MW by 2030. As of 2023, the installed capacity stands at 2,417.7 MW, highlighting the need for a substantial increase of 3,382 MW over the next seven years. This translates to an average annual addition of 488 MW, a considerable leap from the historical average of 60 MW per year over the past four decades.

The first geothermal power plant in Indonesia, Kamojang-1, was installed in 1983 with a capacity of 30 MW (Darma, Imani, Shidqi, Riyanto, & Daud, Country Update: The Fast Growth of Geothermal Energy Development in Indonesia, 2021; Mansoer & Idral, 2015). Since then, the growth has been steady but slow, utilizing only about 10% of the total geothermal resources. The current pace of development underscores the necessity for massive exploration activities to identify and develop new geothermal resources. Figure 1 shows the historical and target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

To meet the 2030 target, Indonesia should enhance its exploration efforts and adopt comprehensive de-risking measures. Exploration involves identifying viable geothermal resources, which requires significant investment and technological expertise. De-risking strategies, such as the Geothermal Resource Risk Mitigation (GREM) program, are essential to reduce the financial risks associated with exploration and early-stage development.

These efforts will not only accelerate the development of new geothermal projects but also ensure that the projects are financially viable and sustainable. By addressing the exploration and risk challenges, Indonesia can unlock its vast geothermal potential, contributing significantly to the country's renewable energy goals and sustainability target.

1.1 Opportunity and Challenges of Geothermal Business

The geothermal sector in Indonesia holds significant market potential, particularly due to the concentration of current reserves in Sumatra and Java, regions with substantial electricity demand. These areas are heavily reliant on coal-fired power plants, which are being phased out under a program initiated by the Government of Indonesia (GoI). This strategic move to reduce coal dependency presents an opportunity for geothermal electricity generation

to emerge as a viable substitute (Fadhillah, et al., 2023). Geothermal energy, capable of providing baseload power, is expected to replace coal as the primary source of power generation in Indonesia (World bank, 2011).

Despite its promising potential, the geothermal industry in Indonesia faces significant challenges in attracting investors. The high risks associated with geothermal projects are not adequately compensated by returns, deterring investment. Development projects frequently encounter obstacles during the transition to the production phase, including unfavorable economic conditions, limited resource availability, and social concerns. The industry's progression is influenced by a complex interplay of political, economic, social, and technical (Komendantova, et al., 2012; IRENA, 2022). Figure 2 shows the general problem of Indonesia geothermal project based on Fadhillah (Fadhillah F. R., Economic Evaluation of Bravo Geothermal Prospect in Participating Green Energy Effort, 2023).

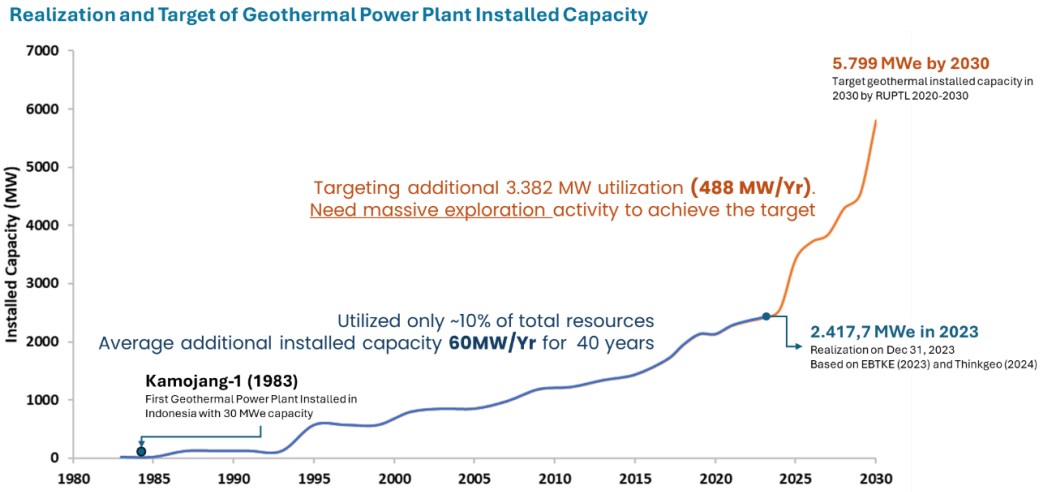

Figure 1: Target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

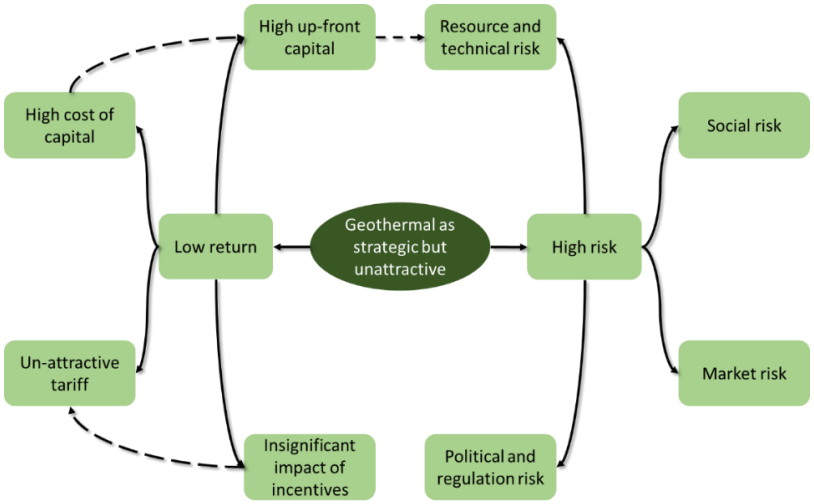

Figure 2: The problem tree of general Indonesia geothermal project.

1.2 Research Objective

The primary objective of this research is to provide geothermal developers with review to navigate and comply with lender procurement guidelines. This strategy is aimed at enhancing project viability and promoting the wider adoption of geothermal energy exploration in Indonesia by clarifying the processes involved and suggesting methods to alleviate administrative burdens associated with these processes.

2. INDONESIA GEOTHERMAL BUSINESS OVERVIEW

2.1 Geothermal Project Stage

The geothermal business process, especially for electricity generation, mainly consisted of preliminary survey, exploration, test drilling, project review, field development, power plant construction, commissioning, and production phases (ESMAP, 2012; IGA, 2014). A geothermal company in Indonesia is eligible to perform

preliminary survey until feasibility study for 7 years maximum. The company that successfully reaches commercial operation date (COD) would obtain 30 years of license, Conversely, in cases where an area is found unpromising for geothermal development during the preliminary survey and feasibility study phase, the company is obliged to relinquish the rights to that specific area to the government (Purba, et al., 2021; GoI, 2014). The summary of Indonesia geothermal project stages shown in Figure 3 based on (Fadhillah F. R., Economic Evaluation of Bravo Geothermal Prospect in Participating Green Energy Effort, 2023).

In the exploration phase of geothermal development in Indonesia, the government has launched several initiatives and introduced specific terminologies to support the process. These measures are intended to reduce exploration risks and encourage a favorable investment climate (Apriani, et al., 2023). Below are some of the key government-implemented schemes and terminologies (Table 1):

In Indonesia's geothermal industry, electricity generation is the primary product and main revenue source. Under common business practices, steam or electricity is sold to Perusahaan Listrik Negara (PLN), the state-owned electricity company, which is the exclusive buyer. This gives PLN considerable influence in the market, particularly in setting tariffs, which often benefits the company (Fadhillah F. R., 2023). Subsequently, PLN also transmits and distributes electricity to consumers across various sectors, including industrial, commercial, and residential users (Brilian, et al., 2024). This arrangement is known as the on-grid model.

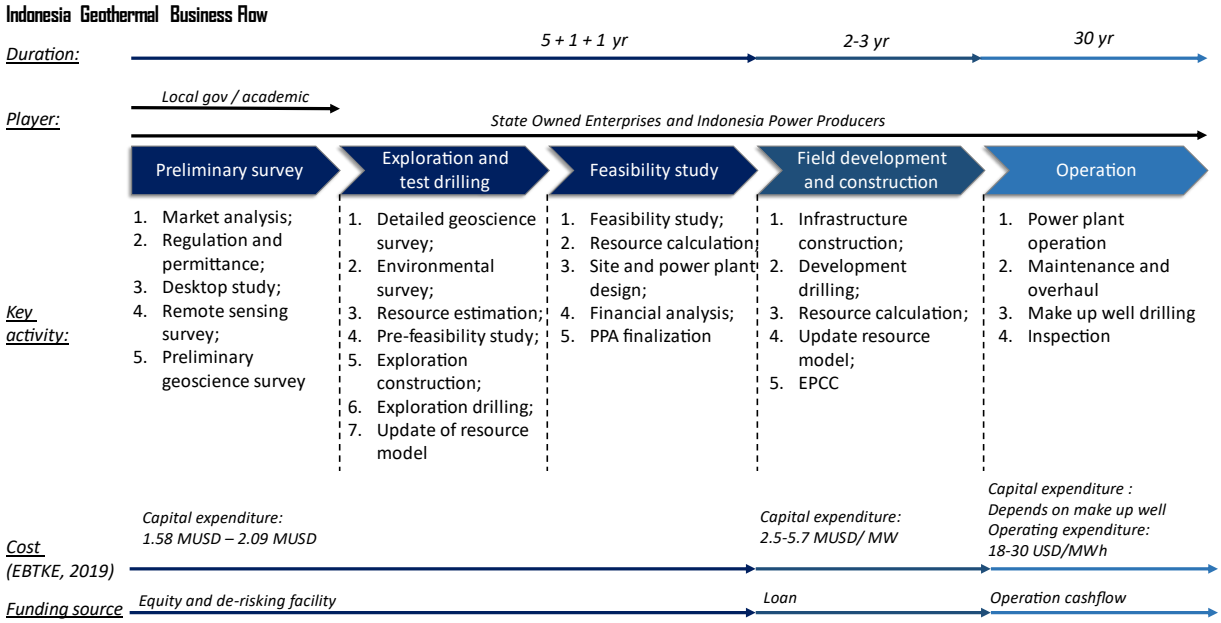

Figure 3: Indonesia geothermal business flow modified from GoI (2014), Purba (2021), and ESDM (2022).

Table 1: Geothermal exploration schemes and terminologies in Indonesia.

***Wilayah Terbuka* (Geothermal Open Area)**	An area suspected of having geothermal potential outside the coordinate boundaries of a Geothermal Working Area
Assignment Area	A Geothermal Open Area with certain coordinate boundaries offered to an Other Party for PSP or PSPE
WKP (Geothermal Working Area)	An area with defined coordinate boundaries used for the exploitation of Geothermal for Indirect Use (power)
***Penugasan Survei Pendahuluan*/PSP (Preliminary Survey Assignment)**	The assignment given by the Ministry of Energy and Mineral Resources to carry out the Preliminary Survey activity
***Penugasan Survei Pendahuluan dan Eksplorasi/PSPE* (Preliminary Survey and Exploration Assignment)**	The assignment given by the Ministry of Energy and Mineral Resources to carry out the activities of the Preliminary Survey and Exploration
***Izin Panas Bumi/IPB* (Geothermal License)**	Permit to conduct exploration and/or exploitation of Geothermal for Indirect Utilization in certain working areas
Government Drilling	Scheme for government to conduct the early stage of geothermal development (preliminary survey and exploration drilling)

2.2 Goods and Services in Geothermal Exploration Procurement

Understanding the goods and services essential for a geothermal exploration project holds pivotal significance for successful project outcomes. Precise comprehension aids in meticulous project planning by accurately assessing required resources for tasks like drilling and geological assessments. This knowledge is crucial for effective budgeting, preventing financial constraints and ensuring optimal allocation of funds for procurement, equipment rental, and specialized services (Amir Aryani, 2023).

Additionally, recognizing the required goods and services enhances procurement planning, encouraging early engagement with suppliers and fostering robust competition among them. This profound understanding also facilitates better communication and collaboration within project teams, aligning efforts with project objectives, reducing miscommunications, and boosting project management effectiveness. In essence, knowing precisely what goods and services are needed for geothermal exploration is crucial for efficient resource management, transparent procurement activities, and strong team cohesion, all of which play a pivotal role in the success of the project.

3. LENDER PROCUREMENT GUIDELINE IN GREM FACILITY

Lender procurement guidelines comprise standardized protocols and principles formulated by financial institutions to regulate procurement activities across diverse projects and initiatives. These guidelines strive to promote transparency, fairness, and efficiency in selecting suppliers, contractors, and service providers for projects financed by these institutions. Crafted to address a broad spectrum of procurement operations on an international scale, these rules are crucial for maintaining integrity throughout the procurement cycle. Additionally, these guidelines take into account several critical aspects specific to geothermal projects during the procurement process.

The initial financing mechanism for geothermal energy projects typically relies solely on support from international financial institutions. This form of backing is crucial, especially given the substantial costs associated with geothermal exploration and development. Institutions such as the International Bank for Reconstruction and Development (IBRD), the Asian Development Bank (ADB), the Japan Bank for International Cooperation (JBIC), the World Bank (WB), and the Japan International Cooperation Agency (JICA) play significant roles in this sector by providing financial backing that underpins many of the early and capital-intensive stages of geothermal projects, ensuring that such renewable energy initiatives can get off the ground.

Lender procurement guidelines, established by these institutions, are essential for governing how funded projects proceed with acquiring goods, services, and works. These guidelines are designed to foster a procurement process that is transparent, fair, and efficient, helping to prevent corruption and ensuring that contractors and service providers are selected based on merit and capability, which is vital for the successful completion of any project. Consideration factors within lender procurement guidelines encompass several key areas:

First, adherence to lender procurement guidelines ensures compliance with the standardized instructions and principles established by lending institutions. This adherence fosters transparency, fairness, and efficiency in the procurement process, specifically tailored to address needs unique to the geothermal sector such as drilling equipment, geophysical surveys, resource assessment, and environmental considerations.

Risk mitigation strategies are also pivotal, focusing on addressing geological uncertainties and the technical complexities inherent in geothermal exploration projects. These strategies include conducting thorough background checks on vendors, suppliers, contractors, and other involved parties to mitigate risks associated with fraud, corruption, or conflicts of interest, and implementing penalties, sanctions, or legal actions if fraudulent activities are detected.

Compliance with global issues is critical, involving the evaluation of borrower countries based on factors like gender equality, environmental concerns, social impact, and stability in conflict-prone areas. Contractors failing to meet these global issues requirements, including those related to gender-based violence and discrimination, are subject to disqualification.

Counterterrorism measures require screening contractors and consultants to ensure they are not involved in any terrorist activities and verifying that winning bidders or recommended consultants are not on the lenders' debarred lists before contract signatures.

Lastly, procurement process monitoring is conducted through the use of online systems that track every step from the identification of needs to contract management. This includes uploading relevant procurement documentation for lender review, especially for packages that require prior approval. These measures collectively ensure a robust, secure, and compliant procurement process aligned with international standards and lender expectations.

3.1 Requirements and Implications for Project Developers

Lenders typically impose a set of requirements on developers managing geothermal exploration projects, which serve as prerequisites for securing funding and ensuring efficient procurement processes. One such requirement is the preparation of a comprehensive procurement strategy that details the developers' analysis to identify the most suitable procurement method. This strategy allows for flexibility in designing approaches that maximize cost-effectiveness and align with project objectives, thus providing a strong foundation for successful project implementation. The implications of this include giving developers insight into the project's procurement needs and potential challenges, allowing for tailored procurement strategies that align with project objectives, enhancing the likelihood of achieving cost-effectiveness, and providing a framework for effective project management and risk mitigation.

Furthermore, developers are required to ensure that contractors and consultants are not on the lenders' debarred list. Engaging only qualified parties helps maintain the integrity of the procurement process and trust with lenders, ensures compliance with lender requirements, and minimizes legal and financial risks. This process is crucial in facilitating the selection of competent contractors and consultants for efficient project execution.

Another critical aspect is adherence to the principle of fairness in procurement processes, often challenging local content requirements that favor local manufacturers. This adherence ensures impartiality and transparency and may lead to conflicts between government regulations and lender requirements. Developers are challenged to balance compliance with local regulations and international procurement standards, highlighting the importance of addressing regulatory conflicts early in project planning to minimize delays and complications.

Finally, general terms and conditions of contracts are stipulated, requiring that contracts awarded through International Competitive Bidding (ICB) be in English, and that international arbitration takes precedence over national arbitration. This requirement aligns with international procurement and contract management standards and ensures consistency and clarity in contractual agreements. It also facilitates international cooperation and trade by standardizing contractual language and arbitration procedures, promotes adherence to internationally recognized procurement and contract management best practices, and encourages developers to familiarize themselves with global standards and regulations, enhancing their competitiveness in international markets. These collective measures help developers navigate the complex landscape of geothermal project financing effectively..

3.2 Impact of Lender Procurement Guidelines on Geothermal Project Exploration Planning

Developers to meticulously align their exploration planning with lender procurement guidelines. These guidelines profoundly impact the planning stages of geothermal projects, which are inherently capital-intensive and complex. The influence of these guidelines manifests in several critical areas:

1. **Project Viability Assessment**: Lenders require a detailed viability assessment of geothermal projects before providing financing. This assessment includes geological, technical, and economic evaluations to determine if the project is financially viable. Exploration plans must, therefore, align with these stringent assessment criteria to ensure the project is deemed financially sound.
2. **Technical Expertise**: Lenders often stipulate that the project team must possess the necessary expertise in geothermal exploration and development. This requirement impacts exploration planning by necessitating the involvement of skilled geologists, engineers, and other specialists right from the project's inception, ensuring that all technical aspects are handled by experts.
3. **Environmental and Regulatory Compliance**: Stringent compliance with environmental and regulatory standards is a common requirement from lenders. Exploration plans must include detailed environmental impact assessments and ensure all necessary permits are obtained. Compliance with local, state, and federal regulations is crucial, as failure to meet these standards can lead to the denial of financing.
4. **Resource Assessment**: Lenders seek assurances that the geothermal resource is well-defined and sustainable. A comprehensive resource assessment is critical, providing detailed data on the resource's size, temperature, and productivity. Such assessments must adhere to industry standards and best practices to meet the stringent requirements set by lenders.
5. **Risk Mitigation**: Given the risk-averse nature of lenders, exploration plans must include thorough risk assessments and mitigation strategies. These strategies should address potential issues such as drilling risks, reservoir performance uncertainties, and equipment reliability to assure lenders of the project's feasibility and security.
6. **Cost Estimation**: Accurate and detailed cost estimation is essential for lenders to evaluate the financial requirements and economic feasibility of a project. Exploration planning should encompass detailed cost estimates covering all aspects of the project, from exploration activities and drilling to equipment procurement and infrastructure development. These estimates must align with lender criteria and industry standards to ensure accuracy and reliability.

7. **Project Timeline**: Lenders typically have specific expectations for project timelines, from exploration to resource confirmation and overall project development. Delays in any phase of exploration can adversely affect financing and the project's economic prospects. Hence, realistic and carefully considered timelines are crucial components of exploration planning.

Providing comprehensive and precise information in a funding proposal is vital. This includes details about the project's goals, technical specifications, expected outcomes, budget, timeline, and procurement plans. Information about the management team's experience, market demand, and competitive landscape also plays a crucial role. Such detailed submissions not only build trust with lenders but also enhance the likelihood of securing necessary funding by demonstrating the project's potential for success and capacity to meet financial obligations.

4. CHALLENGES TO FOLLOW THE LENDER PROCUREMENT GUIDELINE

The procurement process is a structured and strategic approach for acquiring goods, services, or works from external suppliers or contractors. This process generally unfolds through several key steps: identifying procurement needs and specifications, selecting suppliers, negotiating contracts, and managing these contracts. The sequence includes conducting market research, prequalifying suppliers, issuing requests for proposals or bids, evaluating these proposals, and overseeing supplier relationships.

Effective procurement processes are designed to ensure transparency, foster competition, achieve value for money, and comply with legal and regulatory standards. While the specifics of the process can vary by organization, industry, or project, the primary aim is to acquire the appropriate goods and services, at the right time and cost, in the correct quantities, all while maintaining quality and managing risks.

The procurement process, however, is fraught with challenges and risks. Key issues include identifying reliable suppliers capable of meeting the demands for quality, quantity, and timing—failures here can lead to project delays, subpar products, and increased costs. Legal and regulatory compliance is critical to avoid disputes, penalties, and potential damage to reputation. Additionally, procurement timelines may need extensions, especially for packages requiring prior lender review, to accommodate the time needed to receive no objections from the lender.

The process is also vulnerable to unethical practices such as bid rigging, bribery, and kickbacks, which can result in financial losses and tarnish an organization's integrity. Managing risks related to supplier reliability, delivery delays, and market fluctuations requires proactive risk mitigation strategies and comprehensive contingency planning. Balancing ethical considerations, such as environmental and social impacts within the supply chain, presents its own set of challenges. Ensuring responsible practices while maintaining cost efficiency demands a careful balance.

Moreover, navigating the complex web of domestic and international legal and regulatory frameworks is a significant challenge that requires meticulous attention to detail. Promoting transparency and fairness in procurement is crucial to preventing favoritism, bias, and corruption, ensuring that evaluations are consistent and objective, and mitigating conflicts of interest.

Understanding procurement guidelines is vital for all project stakeholders, as these guidelines provide a framework for adhering to legal and ethical standards and fostering an environment of transparency and impartiality during supplier selection. This understanding not only facilitates efficient decision-making but also enhances communication, allowing stakeholders to synchronize their efforts effectively. It also plays a crucial role in preemptively addressing potential risks through well-defined risk management strategies, establishing a system of accountability, and optimizing resource allocation. This collective comprehension fosters trust among stakeholders and is essential for the successful completion of projects, aligning efforts with project objectives and timelines.

5. CONCLUSION

The conclusion of the document emphasizes the vital role of procurement in the geothermal business process, particularly under the Geothermal Resource Risk Mitigation (GREM) facility in Indonesia. It highlights the necessity for geothermal developers to thoroughly understand the procurement demands dictated by their selected financial sources. A lack of comprehension regarding these procurement requirements can lead to extended delays, inflated costs, and diminished value of project revenues.

Despite the GREM facility's goal to fast-track the utilization of geothermal energy in Indonesia, its deployment faces notable challenges, especially in the procurement aspect. The paper addresses these issues with the intent to enhance stakeholder awareness of the challenges posed by procurement guidelines required by donors and International Financial Institutions (IFIs). This discussion is meant to foster deeper dialogues to discover an

optimal balance between Donor Requirements, Indonesian Government Regulations, and Company Internal Policies, ensuring that procurement guidelines support rather than hinder project progression.

Looking forward, the paper signals the authors' intention to delve into specific challenges in future discussions. These will focus on two prevalent topics within Indonesian geothermal forums: the implementation of local content requirements (*Tingkat Kandungan Dalam Negeri* / TKDN) in geothermal projects funded by International Donors / IFIs, and the difficulties related to conducting precise market surveys for the development of reliable procurement plans. By concentrating on these particular issues, the authors aim to offer more detailed insights and practical solutions, thereby enriching the ongoing discourse on geothermal development in Indonesia.

ABSTRACT

Indonesia, a top two global leader in geothermal utilization, has set ambitious targets to maximize its utilization of this renewable resource. To achieve these goals, substantial investment is essential, and one of the primary strategies employed by the Indonesian government is the provision of tax fiscal incentives aimed at enhancing the investment climate by reducing costs and risks for investors.

This study conducts a comprehensive literature review to evaluate the effectiveness of global tax incentive approaches for renewable energy development, with a focus on comparing the strategies of Indonesia and the USA—two leading countries in geothermal energy utilization. In Indonesia, the government's support includes tax holidays, tax allowances, import tax exemptions, and land tax exemptions, which are designed to ease financial burdens throughout the exploration and operational phases of geothermal projects. In contrast, the USA utilizes a combination of federal tax credits, specifically the Production Tax Credit (PTC) and the Investment Tax Credit (ITC), to stimulate investments in geothermal energy.

This paper also undertakes an economic evaluation of projects to assess the financial impacts of these tax facilities on project bankability. Using scenario analysis based on published economic data of geothermal projects, the study compares the effects of tax incentives in both countries on project returns and debt repayment capabilities. The findings suggest potential improvements for Indonesia, such as extending the tax holiday period to 10 years post-operation, enhancing land tax exemptions, and better aligning incentives with the phases of positive taxable profit generation. Additionally, the adoption of production tax credit scheme, similarto that of the USA, is recommended to significantly enhance the bankability of geothermal projects in Indonesia. This research provides valuable insights into optimizing tax incentive strategies to attract greater investment and ensure the sustainable development of geothermal energy.

1. INTRODUCTION

The geothermal development in Indonesia has started from colonized era with commercial utilization remarked through Kamojang Geothermal Power Plant (30MW) in 1983. Nowadays, Indonesia is top two geothermal country in the world with 2.417 MW installed capacity from approximately 23 GW total potential. It means that Indonesia only utilized around 10% of total potential with average additional capacity around 60 MW per annum. There are 46 geothermal power plants developed by State-Owned Enterprises (SOE) and Independent Power Producer (IPP) in 17 geothermal working areas.

Government of Indonesia has plan to utilize geothermal as baseload to replace coal power plant and set the target of utilization to reach 5.799 MW in 2030. The government target emphasizes the significant increase in average of additional installed capacity toward 488 MW per annum from 2024 to 2030. This bold target needs to be achieved by catalyzing geothermal investment though better project attractiveness, including from fiscal incentive perspective. Figure 1 shows the historical and target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

1.1 Opportunity and Challenges of Geothermal Business

Indonesia, as a leading nation for renewable energy potential in ASEAN, faces unattractive conditions for renewable investment, including geothermal. Based on ESDM (2022), the geothermal investment realization shows declining pattern during 2016-2021 (Figure 1). The situation contradicts the target to increase geothermal utilization, which requires USD 27 billion additional investment based on SMI (2018). Furthermore, Indonesia is positioned at rank 63 from 132 of the worlds and rank 5 of 10 ASEAN countries related renewable regulation

rank, including the assessment of regulation-incentives support and attribute of the financial incentives for the geothermal (Table 1).

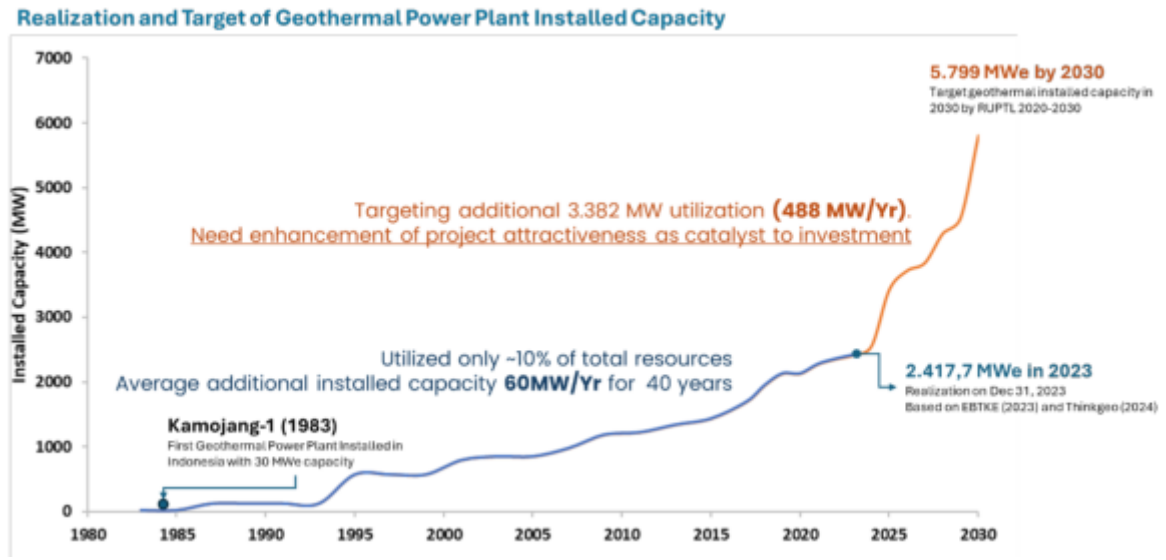

Figure 1: Indonesia geothermal power plant installed capacity and target for 2023 based on EBTKE (2023) and Thinkgeo (2024).

Table 1: The world regulation in sustainable energy rank for ASEAN countries (Vakulchuk, et al., 2022).

Country	Total score	(1) Legal framework for RE	(2) Planning for RE expansion	(3) Incentives and regulatory support	(4) Attributes of financial and regulatory incentives	(5) Network connection and use	(6) Counterparty risk	(7) Carbon pricing and monitoring
Vietnam	467	100	98	79	58	66	66	0
Philippines	437	100	59	77	83	53	65	0
Malaysia	404	100	71	70	58	32	73	0
Singapore	377	100	64	19	67	60	67	0
Indonesia	376	100	66	31	33	13	83	50
Thailand	329	50	56	56	67	20	80	0
Cambodia	289	100	15	18	0	30	76	50
Laos	214	100	55	27	8	7	17	0
Myanmar	195	50	48	34	17	6	40	0

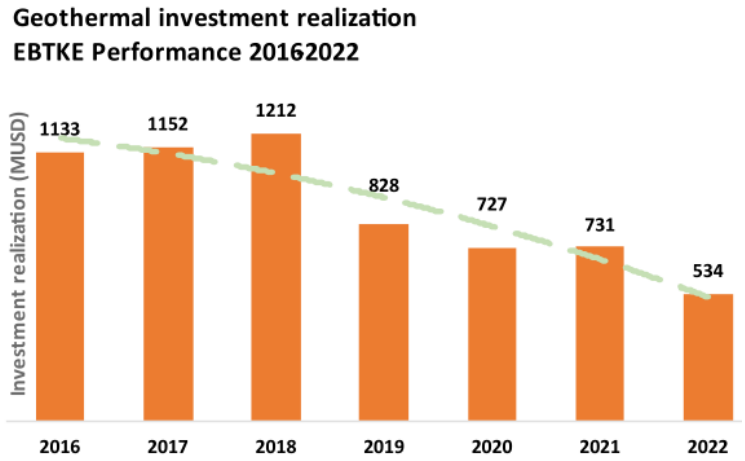

Figure 2: Indonesia geothermal investment realization from 2016 to 2022 (modified from EBTKE, 2022).

The trend of declining geothermal investment realization can be attributed to both internal and external factors concerning project conditions. Internally, the nature of geothermal projects is such that the bulk of investment is typically required during the development phase, particularly during the Engineering, Procurement, and

Construction (EPC) stage. This phase demands significant capital as it involves the construction of infrastructure and power plant necessary for the project's operation.

After the completion of the EPC phase and the onset of the Commercial Operation Date (COD), investment levels generally decline. This pattern could be observed in the substantial investments made in 2016, 2017, and 2018 by major players such as Pertamina Geothermal Energy, Sarulla Operation, and Sorik Marapi Geothermal, which were all in the process of conducting EPC activities in their respective fields.

In 2019, a marked reduction in investment was observed, coinciding with several fields beginning operation, including Lumut Balai, Sorik Marapi, Muara Laboh, Sarulla (2018), and Karaha (2018). As these projects transitioned from the capital-intensive development phase to operational status, the requirement for heavy investment subsided, leading to an overall decrease in the investment figures for the sector.

External factors, including market trends, regulatory environments, economic stability, and fiscal incentives, plays significant role in shaping the investment landscape for geothermal projects, alongside the internal project life cycle dynamics. The country's renewable incentives are underperforming due to the lax enforcement of regulations, which stands in contrast to the more effective incentive structures in Vietnam, Malaysia, and the Philippines. This disparity influences Indonesia's attractiveness to investors and shapes its investment patterns within the renewable sector (Vakulchuk, et al., 2022).

1.2 Problem Statement

The Alpha project, a hypothetical geothermal project in Indonesia, encounters difficulties in providing acceptable return to shareholder. This situation presents significant barrier to project advancement, given the high upfront costs required for resource confirmation and production, alongside the need for commercial financing for development. Author is considering utilizing the government fiscal facility in form of tax holiday to enhance the economic return.

The implementation of fiscal incentives for renewable energy across the world is also assessed to formulate more impactful fiscal incentive from project economic perspective. Author use US tax facility as benchmark since US is nation with most installed geothermal capacity globally.

1.3 Research Question and Objective

The objective of this paper is to provide project economic analysis with recommendations by assessing whether tax facilities provide more significant impact to enhance project return. The research questions are:

1. How is the practice of fiscal incentives practiced across the world?
2. How is the project economic comparison between Indonesian tax facility or US tax facility? Which scenario provides better return?

2. GLOBAL AND REGIONAL PRACTICE FOR FISCAL INCENTIVES

Renewable energy promotion has been performed in various ways, including fiscal-financial, policy-regulatory, researchdevelopment, and voluntary programs (ADB Institute, 2018). Fiscal incentives aim to enhance the investment climate by increasing the business profit with less cost/risk to investors. The incentives provided through several government programs influence the business decision to encourage investment, profitability, and benefits (Chalk, 2001; UNCTAD, 2000). Although government and investors are interested in obtaining more excellent take from the business, Afandi (2017) notes the fiscal incentive should balance the government value (e.g., project acceleration, increasing production) and investor reward (e.g. promising return and risk sharing). Furthermore, the government also aims to boost exploration activity and increase production.

REN21 (2023) analyse the fiscal incentives and investment practices across the nation as shown in figure below. The high-income countries lead in implementing most incentives, with the most common being public investment, loans, grants, capital subsidies, or rebates, observed in 41 countries. This is followed by investment or production tax credits, used by 35 countries, and reductions in sales, energy, CO2, VAT, or other taxes, adopted by 39 countries. Feed-in tariffs or premium payments are also popular, especially in high and upper-middle-income countries, indicating a preference for guaranteed price mechanisms to encourage renewable energy production. In contrast, upper-middle-income countries show a strong preference for net metering or billing, used by 23 countries, allowing consumers to sell surplus energy back to the grid, effectively reducing their energy costs. However, as income levels decrease, the adoption of these incentives generally declines, highlighting the challenges lower-income countries face in funding extensive renewable energy policies. For instance, lower-income countries have lesser engagement with complex fiscal tools like feed-in tariffs and tax credits, primarily using public investments and tax reductions more modestly. This pattern underscores the correlation between a country's economic capacity and the breadth of its renewable energy incentives.

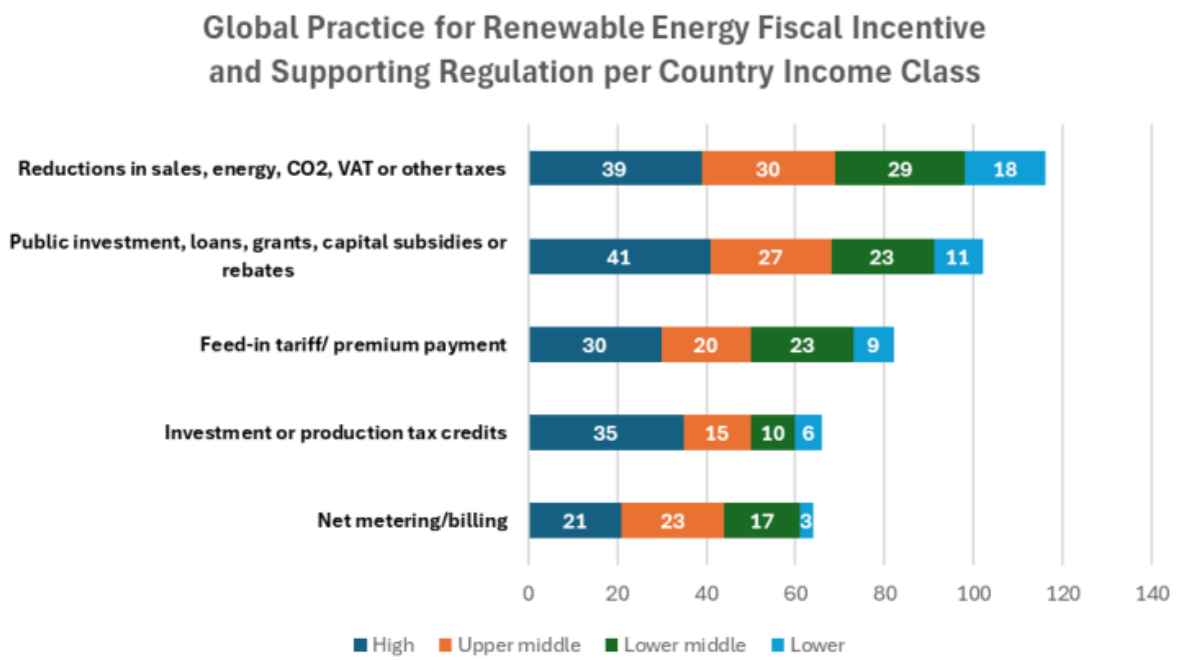

Figure 3: Global Practice for Renewable Energy Fiscal Incentive and Supporting Regulation per Country Income Class.

Asian Development Bank (2018), highlights the recommended strategy of employing fiscal and financial incentives to promote renewable energy, encompassing geothermal resources. This includes mechanisms such as Feed-in Tariffs (FITs), grants, soft loans, and tax incentives:

- Feed-in Tariff (FIT) are policy mechanisms designed to promote the deployment of renewable energy technologies by providing adequate compensation above the electricity market price. This compensation incentivizes investors to accelerate their investments in renewable energy technologies and reduce uncertainties associated with their deployment. FITs have significantly deployed renewable energy technologies in Europe, especially in Germany, Spain, and France. The policy mechanism has accelerated investment in renewable energy technologies and boosted their development in these countries. The compensation provided by FITs has provided investors with the necessary financial incentives to invest in renewable energy technologies. It accommodates the high upfront costs associated with renewable energy technologies.
- Grants have emerged as a critical mechanism for promoting the deployment of renewable energy technologies, particularly in developing countries. Othman, et al. (2019) and Hemphill (2015) emphasizes that grants provided by international organizations (e.g. World Bank, the International Finance Corporation (IFC), and the Global Environment Facility) have played a significant role in promoting the deployment of renewable energy in developing countries. Grants used to enhance the profitability by providing additional cash flow to the project through the investment grant program. The grants also could be utilized to enhance project deliverability by providing technical assistance in the preparation of bankable resource assessment, environmental-social impact assessment, technical design, financial model, and supporting document (ADB, 2019).
- Soft loans have become an increasingly alternative financing mechanism for renewable energy projects, particularly in developing countries. IRENA (2020) mention that soft loan positively reduces the cost of capital for renewable energy projects, enhancing financial viability and investment attractiveness. Soft loans also reduce investment risks by providing more extended repayment periods, lower interest rates, and more flexible repayment terms. It would be critical in bridging the financing gap for renewable energy projects, enabling greater access to capital for developers, and facilitating the deployment of renewable energy in the developing country (Bhusal, et al., 2021).
- Tax incentives, such as tax credits, deductions, and exemptions, have significantly encouraged the development of renewable energy projects in the United States. Hemphill & Sampson (2015) emphasizes that tax incentives have impact to increasing the attractiveness of renewable energy projects to investors.

According to Rio (2014), the fiscal incentives for renewable energy generally launched to boost the utilization of renewable energy using collaborative approach between instruments. Vakulchuk, Overland, & Suryadi (2022)

summarize the fiscal incentives that applied for renewable energy in ASEAN that emphasize the practice of multi-instrument deployment to support renewable energy development as shown in Figure 4.

Sources REN21 (2019, 2022), ACE (2020)

Figure 4: The renewable energy incentives application in ASEAN (Vakulchuk, et al., 2022).

ASEAN Center for Energy (2022) emphasizes several incentives seems be success program to boost renewable energy in ASEAN. The success program, such as:

- Attractive Feed in Tariff (FITs) applied in the Philippines, Malaysia, and Vietnam. The attractive FIT enhances the renewable energy project attractiveness through fair margin for the developer. In Vietnam, the development of renewable energy is accelerated after the implementation of FIT. While the Philippines used the FIT schemes to provide the abovemarket tariff certainty to renewable energy investors for 20 years project period.
- Tax exemption applies to Vietnam, Malaysia, Indonesia, and the Philippines. The tax exemption is applied to reduce the government's take for better rewards to renewable energy investor.
- Private investment in transmission lines was applied in Vietnam to enhance the connectivity of green power plants to the national electricity grid. The transmission line is essential to distribute the produced electricity to the off taker.
- Net metering applied in Malaysia. The implementation of net metering success in accelerating the investment for solar panels allows consumers to install rooftop solar systems, generate electricity for their consumption, and sell any excess electricity to the government.

3. COMPARISON BETWEEN US AND INDONESIA FISSCAL INCENTIVES

3.1 United States Practice

The United States' geothermal installed capacity as of 2023 have reached 3,771 MW after the first GPP COD back in 1971 at the Geysers, putting United States as the nation with the largest geothermal installed capacity globally. There are two key enablers to geothermal development in the United States:

1. Federal and state-level policy support;
2. Fluctuating natural gas prices; and
3. Oil and gas industry maturity.

The policy support is embodied in the form of two waves of policies enactment. The first wave occurred in the 1970s by providing federal land leasing regulation for geothermal developments, exploration de-risking programs, open-access exploration data, investment tax credit, and the market creation for GPPs operated by investors. Meanwhile, the second wave came in the 2000s through royalties, cash grants, production tax credit, and other state-level incentives provided to geothermal power producers as well as mandating a certain amount of renewable electricity that must be sold by utility companies at the state-level. The federal budget for geothermal activities during these two periods was also increased, hence stimulating geothermal development. Furthermore, these two periods of policy support coincided with the spiking natural gas prices during these periods, hence making geothermal electricity more competitive

3.1.1 Production tax credit

The Production Tax Credit (PTC) is a significant financial incentive designed to promote the generation of electricity from renewable energy sources, including geothermal energy, in the United States. The PTC offers a per kilowatt-hour (kWh) tax credit for electricity produced during the first 10 years operation, effectively reducing the tax expenses of the project and enhancing its financial viability.

The PTC rates range from 0.55 to 2.75 cents per kWh of electricity produced. Additionally, there are supplementary bonuses available to further incentivize the use of domestic content and support energy communities. Specifically, a domestic content bonus provides an additional 0.1 cents per kWh, and an energy community bonus offers an extra 0.1 cents per kWh, enhancing the overall value of the tax credits available to geothermal projects.

Eligibility for the PTC requires annual claims for the first 10 years following the commercial operation date (COD). The formula for calculating the PTC is:

PTC = generation capacity per year (kWh)
× (PTC rates + domestic content bonus + energy community bonus)

3.1.2 Investment tax credit

The Investment Tax Credit (ITC) is a crucial financial mechanism aimed at incentivizing investment in renewable energy projects, including geothermal energy, by reducing the tax liability for a percentage of eligible investment costs during the tax year. Unlike the Production Tax Credit (PTC), the ITC is an upfront tax credit that does not depend on the system's performance but rather on the initial capital expenditure.

The ITC rates range from 6% to 30% of the eligible investment cost, with additional bonuses to further enhance its value. Specifically, projects can receive a domestic content bonus and an energy community bonus, each adding an additional 10% of the eligible investment cost. These bonuses are designed to promote the use of domestic materials and support the economic development of energy communities.

Eligible expenses for the ITC include:

1. Labor Costs: Expenses related to onsite preparation, assembly, and original installation of the geothermal system.
2. Equipment Costs: Costs associated with necessary equipment such as heat pumps, piping, and other components directly linked to the geothermal heat pump system.
3. Onsite Preparation Costs: Costs incurred to prepare the site for installing the geothermal system.

3.2 Indonesia Practice

Indonesia's government has already launched several incentives for geothermal such as tax holiday/tax allowance, import tax exemption, and land tax exemption as shown in Figure 5. EBTKE (2022) emphasizes that the tax facility could reduce the levelized cost of electricity (LCOE) by 0.07-0.19 US cents/kWh. The explanation of each tax facility as below:

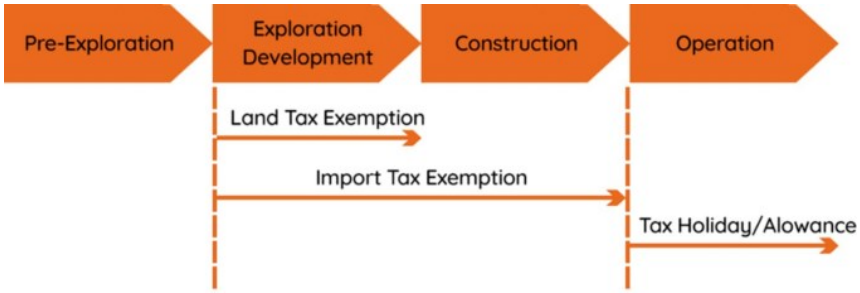

Figure 5: The effective period of Indonesia geothermal tax incentives per project period modified from EBTKE (2021).

The Government of Indonesia offers various fiscal incentives to promote investment and profitability in the geothermal industry. These incentives aim to create a favorable investment climate by reducing business costs and risks for investors. The incentives are provided through different government programs, encouraging businesses to invest in geothermal projects to maximize benefits. (Chalk, 2001) (UNCTAD, 2000). Based on EBTKE (2022; 2021), Lesmana et al (2020), Winofa et al (2020), Abidin (2020), and Fadhillah (2023), current fiscal incentives implemented for the geothermal industry as shown in Table 2.

As indicated by Kristina (2018) and Nugraha et al. (2017), the current tax incentives for geothermal projects in Indonesia have not demonstrated significant impact in enhancing project attractiveness or reducing the cost of electricity generation. The incentives, as per IRENA (2022) and IESR (2022), include a tax holiday that allows for 100% tax reduction for corporate income tax (PPh) for a period of 5 to 20 years. However, this particular incentive has not been effectively utilized, mainly because most renewable energy (RE) developers do not generate taxable profits during the initial five years of project implementation. Fadhillah (2023) provide the case example of ineffective tax holiday period.

Table 2: Current fiscal incentives for geothermal.

Fiscal incentives	Remarks	Effective period of project stage
Tax holiday (PMK 130 / 2020)	The geothermal industry with an investment of more than USD 0.5 trillion would be eligible to obtain 5 years tax holiday. The detail of the tax holiday period as below: - 5 years for IDR 0.5 to 1 trillion investment - 7 years for IDR 1 to 5 trillion investment - 10 years for IDR 5 to 15 trillion investment - 25 years for IDR 15 to 30 trillion investment - 20 years for more than IDR 30 trillion investment The developer would also get the 50% reduction (for more than IDR 0.5 trillion investment) for 2 years during the transition period after the facility. The geothermal developer with more than IDR 0.1 trillion investment is also eligible to obtain 50% tax reduction in the first five years of operation, continued by 2 years transition period that obtain 25% tax reduction (EBTKE, 2021)	Operation
Operation Tax allowance (GR 78/2019)		
• Investment allowance \	Reduction of taxable income equals 5% per year of the total investment for the 6-year period and 30% of the total investment for the full period. The investment should be owned by the main business entity and not transferred during the period (Abidin, et al., 2020; Lesmana, et al., 2020).	Operation
• Accelerated depreciation amortization	Geothermal classified as “class 3” use the double declining balance method with the 8-year period for tangible and intangible asset.	Operation
• Loss carry over	Geothermal industry is eligible to perform loss carry forward for 5-year period with maximum no longer than 10 years. Geothermal as new and renewable energy also eligible to obtain 1 year additional of the facility.	Operation
Land tax exemption (PMK 172/2019)	The land tax for geothermal industry is exempted during the exploration phases (MoF, 2016). The land tax is charged on production phases with guidance to directorate general of tax regulations No. PER-45/PJ/2013.	Exploration
Import tax and value added tax exemption (PMK 172/2016)	Geothermal industry is 100% exempted from import tax for the equipment that not available / adequately produced in Indonesia (Abidin, et al., 2020; Lesmana, et al., 2020). Geothermal industry is not imposed to VAT (Abidin, et al., 2020)	Exploration and development

4. DISCUSSION

Despite the various tax incentives available for geothermal projects in Indonesia, their effectiveness in enhancing project attractiveness and reducing the cost of electricity generation remains questionable. Studies by Kristina (2018) and Nugraha et al. (2017) highlight that these incentives have not significantly impacted the geothermal sector's development.

The current tax incentives, as outlined by IRENA (2022) and IESR (2022), include a tax holiday that provides a 100% reduction in corporate income tax (PPh) for a period ranging from 5 to 20 years. In theory, this should make geothermal projects more financially viable by lowering the tax burden on developers during the early years of project implementation. However, the practical application of this incentive has proven to be less effective.

A key reason for the ineffectiveness of the tax holiday is that most renewable energy developers, including those in the geothermal sector, do not generate taxable profits during the initial years of project implementation. This period is typically marked by depreciation expenses, as non cash and tax deductible expenses. Consequently, the

tax holiday, while generous on paper, offers limited real-world benefits since there are minimal profits to offset with the tax reduction.

Fadhillah (2023) provides a case example illustrating the ineffectiveness of the current tax holiday period. The case demonstrates that the timing and structure of the tax incentives do not align well with the financial realities faced by geothermal developers. Without taxable income in the initial years, the tax holiday does not provide the intended financial relief, thereby failing to improve project attractiveness or significantly reduce electricity generation costs.

Stakeholder feedback on Indonesia tax facility

From the sectoral regulator perspectives, acknowledges the significance of the tax holiday in attracting geothermal developers to Indonesia. However, it is suggested that the current tax holiday could be improved by extending the period, especially for renewable projects. This is particularly crucial for geothermal power plants located in eastern Indonesia, where smaller power plants require more incentives to create an attractive investment climate. The disparity in investment size between eastern and western areas means that the current tax holiday period may not be sufficient for the former. However, ideal government incentives should not overly burden the state budget but should significantly expedite geothermal development. Properly utilized incentives are expected to reduce the need for subsidies allocated to PLN through tariff reductions. Proposals for additional incentives should be well-supported with comprehensive justifications and demonstrate a strong commitment to accelerating geothermal projects affordably.

While the business player views that fiscal incentives like tax holidays need better alignment with the unique financial lifecycle of geothermal projects, which typically start generating positive taxable income around seven years after the commercial operation date (COD). Assuming a project obtains a 10-year tax holiday, the benefits are predominantly realized only during the last three years of the holiday period. Therefore, adjusting the timing of these incentives to coincide with the period when developers begin to generate positive taxable profits would enhance their effectiveness.

5. CONCLUSION

Indonesia has introduced various fiscal incentives to reduce financial barriers and promote the growth of the geothermal energy sector. These incentives include tax holidays/allowances, import tax exemptions, and land tax exemptions. The goal is to make geothermal projects more financially viable and attractive to developers. While stakeholders recognize that these incentives are competitive compared to global standards, they also point out significant bureaucratic inefficiencies that hinder their effectiveness. To further enhance Indonesia's fiscal incentives, the country can draw insights from the US schemes of Production Tax Credit (PTC) and Investment Tax Credit (ITC).

ABSTRACT

Geothermal areas and power plants are frequently surrounded by forests or conservation areas, necessitating careful environmental management to mitigate the impact of energy production on these ecosystems. Since 2008, PT. Pertamina Geothermal Energy (PGE) Kamojang has initiated a comprehensive tree-planting program around well sites and power plants. This program includes the planting of endemic species such as Ki Bereum (Saurauia cauliflora), Lame (Alstonia scholaris), and Ki Honje (Pittosporum ferrugineum), among others, as part of their environmental restoration efforts. The initiative involves stakeholders and the local community in the planning, implementation, and evaluation processes, ensuring a collaborative approach to ecological conservation. Natural forests play a crucial role in regulating greenhouse gas concentrations in the atmosphere, making them integral to a comprehensive response to climate change. According to Brown (1997), plants absorb CO2 from the atmosphere and convert it into organic matter through photosynthesis, a process essential for their growth. This biological function allows plants to capture carbon dioxide and store it in their biomass. To quantify the carbon sequestration potential of the planted trees, measurements are conducted using allometric equations derived from regression analysis for specific tree types or groups, following the guidelines outlined in SNI 7725:2011. These measurements are crucial for understanding the carbon dynamics within the reforested areas and for assessing the effectiveness of the reforestation efforts. The results from planting sites Well KMJ-41 and Well KMJ-32 indicate a total carbon absorption capacity of 2.111 tons CO2 per year. Among the various species, Ki Honje demonstrated the highest potential for carbon absorption, with a value of 0.044 tons CO2. This significant potential is particularly noteworthy given the young age of the plants in these areas, suggesting that their carbon sequestration capacity will increase as they mature. The role of natural forests extends beyond carbon sequestration. Protecting these forests is essential not only for mitigating climate change but also for maintaining the sustainability of the water cycle and supporting geothermal operations. By preserving natural forests and enhancing reforestation efforts, it is possible to create a synergistic relationship that benefits both the environment and energy production. PGE Kamojang's tree-planting program exemplifies how operational activities can be aligned with environmental sustainability goals. By involving local communities and stakeholders, the program ensures that the reforestation efforts are grounded in local ecological and social aspects.

1. INTRODUCTION

PT Pertamina Geothermal Energy in Kamojang, West Java, Indonesia, serves as a critical site for both geothermal energy production and environmental restoration. The restoration management at Kamojang aims to expedite the recovery of former commercial forests to their natural states, introducing elements such as decaying wood, charred wood, deciduous trees, and varied forest structure, which are essential for supporting rare and threatened species. The approach to habitat restoration involves controlled burning and enhancing the quality and continuity of decaying wood, thereby fostering diverse, productive, and multifunctional landscapes resilient to economic fluctuations and climatic changes.

A significant aspect of this restoration effort is its potential for CO2 absorption through tree planting. As a major contributor to global warming, CO2 levels are rising due to industrial activities, motorized vehicle use, power plant emissions, and forest fires. Plants play a crucial role in mitigating these effects by absorbing CO2 during photosynthesis and converting it into organic matter. According to Brown (1997) and Maiti et al. (2015), this process allows plants to capture and store carbon in their biomass, contributing significantly to carbon sequestration. The Intergovernmental Panel on Climate Change (IPCC, 2007) identifies five carbon sources: above-ground biomass, below-ground biomass, dead trees, litter, and soil. The Kamojang area, managed by PGE, possesses substantial vegetation assets that can effectively absorb and store CO2 from these sources. The successful management of vegetation in this area offers a viable solution to combating global warming by maximizing the potential for carbon sequestration and storage.

The primary aim of this research is to determine effective restoration management and forest landscape restoration (FLR) strategies that enhance the ecological and carbon sequestration functions of reforested areas. By focusing on the Kamojang area managed by PGE, the research seeks to develop and implement restoration techniques that promote biodiversity, improve habitat conditions for rare and threatened species, and create resilient forest ecosystems. A key component of this research is quantifying the carbon sequestration potential of the planted trees. This involves conducting precise measurements using allometric equations derived from regression analysis for specific tree types or groups, in accordance with the guidelines outlined in SNI 7725:2011. These measurements are essential for understanding carbon dynamics within the reforested areas and for evaluating the success of reforestation efforts. Accurately quantifying carbon sequestration enables researchers to assess the effectiveness of various restoration strategies and provides valuable data for optimizing future restoration projects to maximize both ecological and climate mitigation benefits.

2. METHODS

2.1 Data Collection

The data collection for this study includes both primary and secondary data. Primary data were obtained by measuring the diameter, height, anwood density of the plants cultivated by PGE Kamojang. Secondary data were gathered from the company's records such as environmental management data including biodiversity conservation.

2.1.1 Determining Plot Size and Number of Plot

Plot size and nu mber of plot determine based on SNI 7724:2011, with a 10% sampling intensity, resulting in a total plot area of about 7,000 m². Seventeen plots of 20m x 20m were established for trees, with sub-plots of 10m x 10m for poles, 5m x 5m for saplings, and 2m x 2m for seedlings, litter, and understory vegetation.

2.1.2 Measurement of Tree

Tree Diameter at Breast Height (DBH) was measured by wrapping a measuring tape around the tree to obtain the circumference, which was then converted to diameter using the formula :

$$d = k / \pi \quad (1)$$

Where k is circumference of the tree and π (3.1416).

Wood Density Wood density was determined by cutting a branch, measuring its volume, and weighing it before and after drying in an oven at 105°C for 48 hours. Tree height was measured using a clinometer, utilizing the concept of similar triangles to calculate the tree height based on the angle of elevation.

2.2. Data Calculation: Biomass and Carbon Sequestration

Biomass was calculated using the allometric equation (Chave,20..), suitable for Kamojang forest condition using the formula :

$$Y = 0.0509 \times \rho \times DBH2 \times T \quad (2)$$

Where Y is a total biomass (g), DBH is diameter at breast height (cm), ρ is wood density (g/cm³), and T is tree height (cm).

Carbon storage was then estimated by converting biomass to stored carbon using a factor of 0.46. Approximately 46% of the biomass content in a tree is carbon. This result is obtained from laboratory results and applies to all types of trees, SNI (2011). The equation is as shown in equation below :

$$\text{Stored Carbon} = Y \times 0.46 \quad (3)$$

After obtaining the value of the carbon stored in a tree, the potential carbon absorption of a tree can be calculated by multiplying it by the ratio of the relative molecular mass of CO2, which is 44, to the relative atomic mass of carbon, which is 12.. Therefore, equation 3 is obtained as follows:

$$\text{CO2 Sequestration} = \text{Stored Carbon} \times \text{Carbon Conversion Factor} \quad (4)$$

Where Carbon Conversion Factor is 3.67.

2.3. Restoration Management

This study utilizes qualitative data to evaluate the restoration management of PGE Kamojang through the Forest Landscape Restoration (FLR) approach and examines adherence to national guidelines. Specifically, it references the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia No. 23 of 2021, which pertains to the Implementation of Forest and Land Rehabilitation, and the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia No. 4 of 2019, which governs the Utilization of

Geothermal Environmental Services in National Parks, Grand Forest Parks, and Nature Tourism Parks, where part of the PGE Kamojang area is designated as a Nature Tourism Park (Taman Wisata Alam).

Table 1: Forest Landscape Restoration (FLR) Strategies.

Category		Principles
Project Management and Governance		
1	Landscape Scale	FLR should target areas larger than a single site but smaller than an ecoregion
2	Prioritization	Optimize ecological and human outcomes, considering social, economic, political, and ecological factors
3	Legal and Normative Compliance	Programs must comply with applicable laws and local norms (good governance)
4	Participation	Active collaboration with local communities and stakeholders
5	Adaptive Management	Continuous monitoring of ecological and human outcomes
Social Aspects		
6	Enhance Livelihoods	Improving local livelihoods through financial outcomes, poverty alleviation, food security, and non-material benefits like landscape beauty and recreation.
7	Inclusiveness and Equity	Programs should benefit all stakeholders, emphasizing gender equality and support for marginalized groups.
8	Capacity Building	Local stakeholders should be provided with scientific and technical information, and programs should build capacities for active participation, informed by local and indigenous knowledge
Ecological Aspects		
9	Biodiversity Conservation	Protect native ecosystems and species
10	Landscape Heterogeneity and Connectivity	Programs should enhance landscape functionality,
11	Provision of Ecosystem Goods and Services	Ensure the provision of ecosystem services such as carbon storage, natural pest control, pollination, ecotourism, and the supply of water, food, timber, and non-timber products, while minimizing trade-offs.

2.3.1 Forest Landscape Restoration (FLR)

The effectiveness of forest landscape restoration (FLR) is evaluated based on principles encompassing project management, human aspects, and ecological aspects. These principles guide the assessment of FLR's ability to regain ecological integrity and enhance human well-being. This table summarizes the key principles under each category for Project Management and Governance, Human Aspects, and Ecological Aspects relevant to Forest Landscape Restoration (FLR) initiatives.

2.3.2 National Law

The holders of the IPJLPB Exploitation and Utilization permit, as referred to the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia No. 4 of 2019 in Article 35 paragraph (3) letter b, that shown in Table 2.

Table 2: Indonesia National Law Requirements.

No	Requirement	Description
1	Area Protection	Conduct protection and security activities in the permitted area, including preventing illegal logging, wildlife hunting, encroachment, settlement, and forest fires.
2	Tree Replacement	Do not cut down trees; if cutting is necessary, replace the trees at a ratio of 1:100 with seedlings to be planted in locations designated by the local UPT and maintained until the end of the permit.
3	Replanting	Plant and maintain vegetation for five years in utilized areas that are no longer in use.
4	Compliance with Environmental Permits	Follow the requirements stated in the Environmental Permit (AMDAL) documents.

3. RESULT AND DISCUSSION

3.1. Forest Landscape Restoration (FLR) Analysis

PGE Kamojang restoration program meets all the criteria for effective project management and governance through the application of the Forest Landscape Restoration (FLR) approach. The project targets areas that are larger than a single site but smaller than an ecoregion, ensuring comprehensive restoration efforts through GIS mapping and land use checking. Prioritization is given to sites that promise increased ecological benefits and fast-growing tree species such as Kihonje. Compliance with legal and normative requirements is strictly adhered to, supported by policies, law enforcement, and land tenure governance. Ecological and socio-economic monitoring is conducted through environmental-social mapping, and a Biodiversity Action Plan (BAP) is implemented alongside environmental studies. Active participation from local communities and stakeholders is encouraged through inclusion in planning, management, and monitoring processes, as well as environmental workshops and multi-sectoral collaboration with stakeholders and NGOs. Adaptive management practices are employed, with continuous monitoring of ecological and human outcomes, ensuring the project's sustainability and effectiveness.

Figure 1: Implementation of Project Management & Governance in PGE Kamojang Forest Landscape Restoration (FLR).

Restoration strongly emphasizes biodiversity conservation, aiming to restore the populations of endemic species within the geothermal operation area. To accelerate plant growth and enhance biodiversity, the project employs the Miyawaki planting method, which is known for its ability to create dense, native forests in a short period. This approach not only promotes rapid vegetation growth, but also contributes to the resilience of the ecosystem in the geothermal area. In terms of promoting ecosystem services, the restoration efforts focus on several critical functions. Natural recharge for water resources is enhanced, ensuring the sustainability of water supplies that are used for geothermal operations. The project also plays a significant role in carbon storage, helping to mitigate climate change by sequestering carbon dioxide. Soil protection is another key benefit, as the restored vegetation helps prevent soil erosion and degradation. Additionally, the restoration project contributes to disaster management, specifically by mitigating the risk of landslides through improved vegetation (vetiver) cover and root systems that stabilize the soil. From an ecological perspective, the project aims to increase landscape heterogeneity. By utilizing various restoration and planting methods, including the cultivation of multiple tree species, the project enhances the structural diversity of the landscape. This heterogeneity is crucial for creating a robust and resilient ecosystem capable of withstanding environmental stresses and supporting a wide range of wildlife species.

Workers in the restoration activities receive monetary income, providing direct financial support to the individuals involved. Additionally, the project promotes economic diversification by encouraging the production and sale of organic fertilizer, offering an alternative source of income for local farmers. Further, the provision of seeds for the restoration project creates another stream of monetary income, helping to sustain the economic well-being of the community. Capacity building is a central component of the project, empowering local communities and stakeholders to actively implement and monitor the restoration program. Through workshops and training sessions, participants gain valuable skills and knowledge in conservation techniques, environmental management, and sustainable practices. Conservation education is also emphasized, raising awareness about the importance of biodiversity and ecological health. From a social perspective, the project prioritizes inclusiveness and equity. Gender equality is promoted by involving women local farmers in nursery plantation activities, ensuring that

women have equal opportunities to benefit from the project. The restoration project fosters local empowerment by opening up job opportunities, thereby strengthening the community's economic resilience and social cohesion.

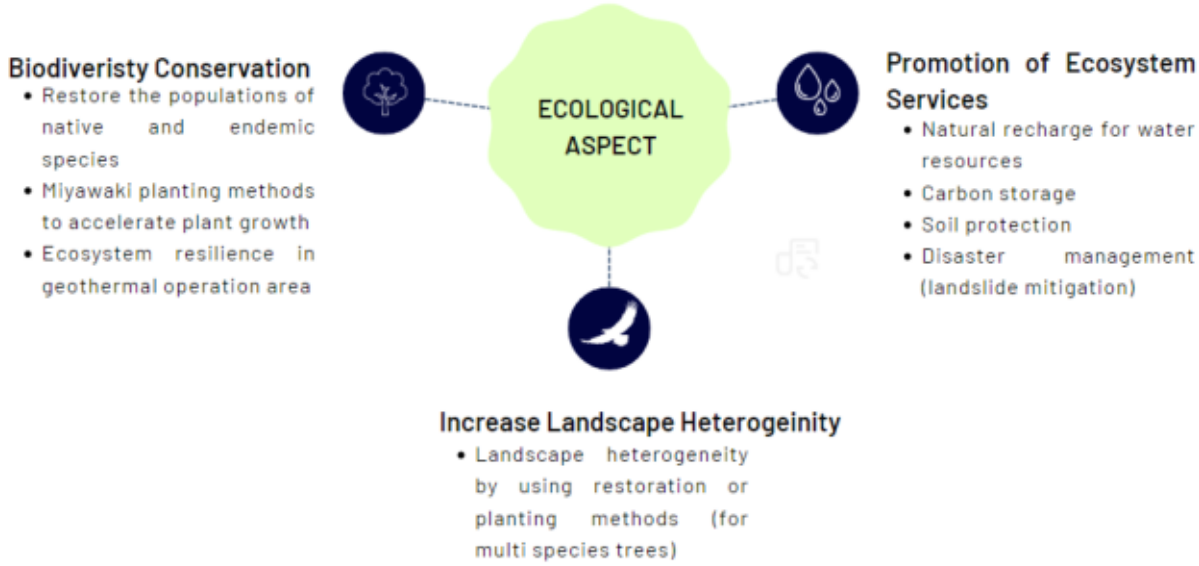

Figure 2: Implementation of Ecological Aspect in PGE Kamojang Forest Landscape Restoration (FLR).

Figure 3: Implementation of Social Aspect in PGE Kamojang Forest Landscape Restoration (FLR).

Table 3: Indonesia National Law Compliance Analysis.

No	Requirement	Description	Analysis
1	Area Protection	Conduct protection and security activities in the permitted area, including preventing illegal logging, wildlife hunting, encroachment, settlement, and forest fires.	PGE Kamojang have implemented comprehensive protection and security measures in the designated area. These activities include regular patrols to deter illegal logging and wildlife hunting every shift, monitoring systems (CCTV & security portals), and fire prevention strategies such as firebreak and community awareness programs
2	Tree Replacement	Do not cut down trees; if cutting is necessary, replace the trees at a ratio of 1:100 with seedlings to	PGE Kamojang adhere strictly to the no-cutting policy. This tree replacement strategy effectively

No	Requirement	Description	Analysis
		be planted in locations designated by the local UPT and maintained until the end of the permit.	compensates for any loss of trees, promoting reforestation and ecological balance.
3	Replanting	Plant and maintain vegetation for five years in utilized areas that are no longer in use.	PGE Kamojang consistently replant and maintain vegetation in areas that have been utilized and are no longer in active use. This replanting process is carried out over a five-year period, ensuring that the restored areas achieve a stable and self-sustaining ecosystem. Tofal replantation from 2008-2023 are 632,052 trees with success growth ratio > 85%.
4	Compliance with Environmental Permits	Follow the requirements stated in the Environmental Permit (AMDAL) documents.	The permit holders fully comply with all the stipulations outlined in the Environmental Permit (AMDAL) documents. This includes conducting regular environmental impact assessments, adhering to mitigation measures, and ensuring that all activities within the permitted area align with the environmental standards and regulations specified in the AMDAL. Regular audits and reporting ensure transparency and accountability, demonstrating the permit holders' commitment to environmental stewardship.

3.2. National Law Compliance Analysis

PGE Kamojang as the holders of the IPJLPB Exploitation and Utilization permit, as specified in the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia No. 4 of 2019 in Article 35 paragraph (3) letter b, are mandated to fulfill several key requirements to ensure sustainable and responsible management of the permitted area.

PGE Kamojang as the holders of the IPJLPB Exploitation and Utilization permit have successfully complied with all key requirements specified by the Regulation of the Minister of Environment and Forestry of the Republic of Indonesia No. 4 of 2019 in Article 35 paragraph (3) letter b.

3.2. Carbon Sequestration Analysis

3.2.1 Biomass

The wood density, DBH (diameter at breast height), and height values for each Kamojang endemic tree species were meticulously gathered through precise calculations. These values are critical for understanding the structural properties and biomass of the trees. By obtaining accurate measurements of these parameters, the project can better assess the ecological benefits provided by each species, presented in Table 4.

Table 4: Kamojang Endemic Tree Calculation Result.

Tree Species	Average DBH (cm)	Average Height (cm)	Wood Density (g/cm³)	Average Biomass Value (g)
Ki Bereum (*Distylum stellare*)	1.3	238.89	0.75	14.89
Lame (*Distylum stellare*)	1.68	147.08	0.48	10.13
Ki Honje (*Pittosporum ferrugineum*)	1.86	290	0.51	25.97
Ki Sireum (*Syzygium lineatum*)	1.60	215	0.815	22.69
Salam (*Syzygium polyanthum*)	1.80	235	0.558	21.63
Peutag (*Syzygium densiflorum*)	1.80	200	0.66	21.77

3.2.2 Correlation of Parameters with Biomass Values

According to the research by Uthbah et al. (2017) and Yuliasmara et al. (2009), tree biomass geometrically correlates parallelly with tree diameter and height. In this study, Ki Bereum plants were sampled to determine the correlation between tree diameter and height with their biomass values. The correlation between diameter and biomass can be seen in Figure 4. In the figure, the diameter of Ki Bereum plants shows a parallel correlation with the biomass value contained. With an R2 value of 0.8473, indicating that 84.73% of the biomass value is influenced by the diameter of the plant. Meanwhile, the correlation of tree height with the contained biomass value can be seen in Figure 4. Correlation of tree height with biomass value of Ki Bereum plants shows a reasonably

parallel correlation, but height has a smaller correlation compared to diameter. In the allometric biomass equation, biomass is proportional to the square of the diameter, hence height correlates less with biomass compared to diameter. Tree height has an R2 value of 0.8339, indicating that 83.39% of the biomass value is influenced by the height of the tree.

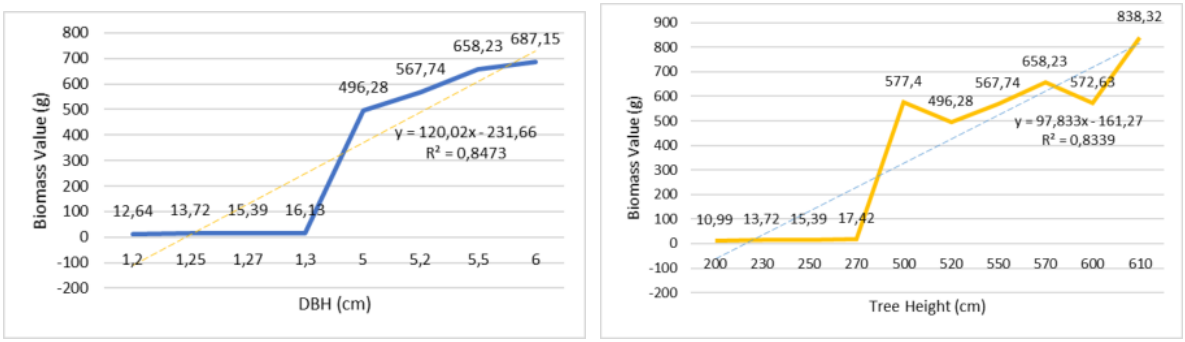

Figure 4: Correlation of DBH (left) and Tree Height (right) with Biomass Value of Ki Bereum.

3.2.3 Carbon Sequestration

Carbon sequestration in each plot is calculated to determine the carbon sequestration potential of the plants cultivated by PGE Kamojang. Carbon sequestration is calculated based on the stored carbon value in each plot, which is then divided by the age of the plants in that area (KMJ-41, 3 years and KMJ-32, 5 years). The average carbon sequestration value in the planting area of well KMJ-41 is approximately 0.218 tCO2/ha/year, with a land area of 5 hectares for the planting area of well KMJ-41, the carbon sequestration capacity in this area is approximately 1.088 tCO2/ha/year.

Table 5: Carbon Sequestration of KMJ-41.

Plot	Total Biomass (g)	Stored Carbon (Kg)	Stored Carbon (Ton/Ha)	Stored Carbon (Ton/Ha/year)	Carbon Sequestration (Ton/Ha/year)
1	150.50	0.069	0.173	0.058	0.212
2	141.58	0.065	0.163	0.054	0.199
3	165.18	0.076	0.190	0.063	0.232
4	158.36	0.073	0.182	0.061	0.223
5	157.78	0.073	0.181	0.061	0.222
				Average	0.218

Carbon sequestration values correlate directly with the biomass of the plants. Therefore, factors influencing biomass values will enhance the carbon sequestration potential of the plants. According to the table above, plants with the highest carbon sequestration values are Salam and Ki Honje plants. This is because these plants have the highest biomass values, which are influenced significantly by their larger diameters compared to other plant species, as indicated in the Table 6.

Table 6: Carbon Sequestration of Kamojang Endemic Tree Species.

Tree Species	Average Biomass Value (g)	Stored Carbon (Kg)	Carbon Sequestration (Ton)
Ki Bereum (*Distylum stellare*)	14.89	0.007	0.025
Lame (*Distylum stellare*)	10.13	0.005	0.017
Ki Honje (*Pittosporum ferrugineum*)	25.97	0.012	0.044
Ki Sireum (*Syzygium lineatum*)	22.69	0.010	0.038
Salam (*Syzygium polyanthum*)	21.63	0.009	0.037
Peutag *(Syzygium densiflorum*)	21.77	0.010	0.037

Carbon sequestration capacity in the planting area of well KMJ-32 is approximately 0.633 tCO2/ha/year. Plot 6 contains Ki Bereum plants, with a land area of approximately 2 hectares the carbon sequestration potential approximately 1,266 tCO2/year. This value is higher compared to the research plot in the KMJ-41 well area., due to the older age of the plants, resulting in greater height and diameter compared to the planting area in the KMJ-41 well area. Therefore, the carbon sequestration potential of both planting areas totals approximately 2,111 tCO2/year.

Figure 5: Kamojang Endemic Trees.

Table 7: Carbon Sequestration of KMJ-32.

Plot	Total Biomass (g)	Stored Carbon (Kg)	Stored Carbon (Ton/Ha)	Stored Carbon (Ton/Ha/year)	Carbon Sequestration (Ton/Ha/year)
6	4669.74	4.752	0.859	0.172	0.633

4. CONCLUSION

The Kamojang restoration management program, utilizing the Forest Landscape Restoration (FLR) approach, has effectively restored biodiversity and ecological health in the geothermal operation area. By targeting areas larger than a single site but smaller than an ecoregion, the program ensures comprehensive restoration through GIS mapping and prioritization of ecologically beneficial sites. Strict adherence to legal requirements, inclusive stakeholder participation, and adaptive management practices have facilitated sustainable project implementation. The use of the Miyawaki planting method has accelerated vegetation growth and biodiversity, enhancing ecosystem resilience. The program also contributes to water resource sustainability, soil protection, and disaster risk mitigation, promoting a robust and diverse landscape.

In terms of carbon sequestration, the Kamojang project has demonstrated significant potential. Detailed measurements of tree species' diameter, height, and wood density have enabled precise biomass and carbon storage calculations. The project shows a direct correlation between biomass and carbon sequestration, with species like Ki Honje and Salam showing the highest values. The calculated carbon sequestration rates for planting areas indicate a substantial capacity to sequester carbon dioxide, totaling approximately 2,111 tCO2/year across different plots. This underscores the project's role in mitigating climate change, enhancing carbon storage, and supporting sustainable environmental practices within the geothermal operation area.

ABSTRACT

Public-private partnerships (PPP) is a collaborative agreement between a public authority and a private or semi-private entity to deliver a public service and in which part of the risks and investments are transferred outside of the public entity's hands, leading generally to long-term agreements. These partnerships can potentially leverage the strengths of both sectors: the public sector's ability to provide regulatory oversight and the private sector's experience, expertise, and efficiency. By sharing risks and responsibilities, PPP can accelerate project timelines, improve service delivery, and foster innovation while reducing the financial burden on the public sector.

Indonesia possesses one of the world's largest geothermal potentials, but only around 10% of it has been utilized. The challenges to further develop geothermal in Indonesia are multi-faceted, including in financing, technical expertise, innovation, and social-ecological concerns. Public-private partnership (PPP) presents a promising development model that can leverage private sector expertise, innovation, and financing, potentially accelerating the advancement of geothermal projects in the country.

The study begins with an introduction to PPP, the potential benefits, and the implementation of PPP, particularly in developing countries. The second part examines geothermal financing in various countries, including Kenya, Turkey, and the US, public and private roles, as well as existing PPP models. These cases are analyzed to identify success, challenges, and the role of government policies and incentives in fostering effective collaborations. Key aspects such as risk allocation, financing structures, and regulatory frameworks, are reviewed to understand their impacts.

The next part of the paper shifts focus to the geothermal landscape in Indonesia. The current state of Indonesia's geothermal sector is reviewed, highlighting the regulatory landscape, the role of government initiatives, and private sector involvements, followed by existing PPP frameworks, and experiences in the geothermal projects. Subsequently, the public and private involvement models and cases are compared with other countries analyzed previously, with different conditions highlighted accordingly. An empirical analysis is performed to identify opportunities for improving the effectiveness of PPP and future potentials of PPP applications, in considerations where international best practices can be adapted. Recommendations are provided to enhance policy frameworks, improve risk management, and streamline project approval processes, including focusing on the importance of creating a conducive investment environment and consistent regulatory policies.

The final part concludes that strategically integrating the best practices of public-private partnerships, customized to Indonesia's unique socio-economic and geological context, can significantly advance its geothermal sector. By drawing on global experiences and developing frameworks tailored to Indonesia's specific conditions, the country can optimize its geothermal potential, thereby enhancing national energy security and achieving sustainable development goals. This comparative analysis provides valuable insights not only for Indonesia but also for other emerging economies aiming to develop their geothermal resources through effective public-private partnerships.

1. INTRODUCTION TO PUBLIC-PRIVATE PARTNERSHIP (PPP)

Significant infrastructure investments are needed worldwide, especially in many developing and emerging economies, to stimulate economic growth and meet environmental goals. According to a report by the Global Infrastructure Hub (2017), the global demand for infrastructure investment, which encompasses energy, telecommunications, transportation (including airports, ports, railways, and roads), and water, is expected to reach $94 trillion by 2040, represents 3.55% of global GDP. An extra $3.5 trillion will also be necessary to fulfill the United Nations' Sustainable Development Goals for electricity and water.

Governments are ultimately responsible for providing public services and the infrastructure required for their delivery. Infrastructure investment is often part of the social contract between a government and its citizens (The World Bank, 2017), and it is probably universally agreed that the state has to play a role in providing public

infrastructure (Yescombe, 2007). However, when the government is faced with pervasive challenges to provide them, considering infrastructures involve huge amounts of capital investment, private investments are often mobilized through public-private partnership (PPP). The capital-intensive nature of basic infrastructure and competition for limited government budgetary resources have prompted governments to invite private investors to fulfill the widening demand-supply gap for infrastructure while the governments are endeavoring to meet the social commitments within the fiscal constraints (Yurdakul et al., 2022).

1.1 Definition, Core Characteristics, and Types

Saussier et al. (2009) defined PPP broadly as an agreement between a public authority (whether at the state or local level) and a private or semi-private entity to deliver a public service and in which part of the risks and investments are transferred outside of the public entity's hands, leading generally to long-term agreements. This definition aligns with Alfen et al. (2009), which describes PPP as "a wide range of arrangements whereby government responsibilities are outsourced to commercial partners, and risk is shared between the public and private sectors to bring about desired outcomes in areas associated with public policy". Alfen et al. (2009) observed various PPP implementation methods as each country adapts the process as appropriate for its own culture, economy, political climate, and legal system. Despite those variations, Iossa & Saussier (2017) identified four primary characteristics of PPPs: (1) task bundling, (2) risk transfer, (3) medium-long-term contracting, and (4) private finance. Table 1 presents a list of various institutions and government agencies' definitions of PPPs, which generally encompass these core characteristics.

Based on the nature of the service and the degree of risk transfer involved in the contracts, PPP contracts can be categorized into two distinct types (Yescombe, 2007; Iossa & Saussier, 2017):

1. "Concession" or also called the financially freestanding project: this is when the private sector's main source of income comes from the user. In these contracts, the private sector revenue is linked to the level of usage or demand for the service. Toll road projects very commonly fall under the concession type.
2. "Availability-based contract" is when the private-sector party mainly sells the service to the public-sector party. In this type of contract, the private sector is partially or all responsible for designing, building, and maintaining the infrastructure and services, but payment from the public sector party is based on the availability of the infrastructure and services, regardless of the level of usage. This model is often used for projects such as hospitals, schools, prisons, waste-water treatment plants, and waste incinerators.

As mentioned in the previous section, one of the common and defining feature of PPP is that it bundles multiple task or phases of a project into a single agreement. The specific responsibilities assigned to the private sector vary depending on the nature of the asset and service involved. Common functions typically include (1) **Design:** developing the project from initial concept and output requirements to construction-ready design specifications, (2) **Build** (when PPPs are used for new infrastructure assets and a private party is required to construct them) or **Rehabilitate** (where PPP involve existing assets and private party is responsible for rehabilitating or extending the asset), (3) **Finance**, (4) **Maintain**, and (5) **Operate** (The World Bank, 2017).

Table 1: Definition of PPP by various institutions and governments.

Institution	Definition
The World Bank (2017)	A long-term contract between a private party and a government entity for providing a public asset or service, in which the private party bears significant risk and management responsibility, and remuneration is linked to performance
Asian Development Bank/ ADB (2008)	A range of possible relationships among public and private entities in the context of infrastructure and other services; present a framework that—while engaging the private sector—-acknowledge and structures the role of government in ensuring that social obligations are met and successful sector reforms and public investments achieved
European Commission (2003)	A partnership between the public sector and the private sector for the purpose of delivering a project or a service traditionally provided by the public sector
UK Government (UK Trade & Investment, 2013)	General term for partnerships that involve everything from operating facilities and providing services on behalf of the public to flexible methods of financing these services
Indonesia Government (Presidential Regulation 38, 2015)	Cooperation between the Government and Business Entity on Infrastructure Provision for the best interest of the Public, in accordance with the pre-determined specifications (by the Minister / Head of Institution / Head of Region/ State-owned Enterprise (SOE) / Regional-owned Enterprise (ROE)), partially or fully uses the resources from the Business Entity while considering risks allocation among Parties.

Based on the above, several types of PPP exist. The most traditional is **BOT (build-operate-transfer)**, in which, as the name suggests, the private sector is responsible for building and operating the asset. The private sector undertakes the investment in capital assets, though the financing comes from the public sector, which also holds the financial risk. When the contract ends, asset ownership is transferred to the public sector according to the terms initially agreed upon unless an extension or renewal of the contract is later approved. Other models include **DBFO (design-build-finance-operate)**, in which the private partner is responsible for the whole stages of the project (Iossa & Saussier, 2017). Table 2 provides a detailed overview of various infrastructure provision models, highlighting the differing public and private sector involvement levels. It illustrates the spectrum from fully public to fully private projects.

Build-Own-Operate (BOO) contract is viewed by some scholars as privatized project (Engel et al., 2020; Trebilcock & Rosenstock, 2015; Yescombe, 2007). Trebilcock and Rosenstock (2015) argue that asset ownership is the key distinction between PPPs and privatization; thus, any arrangement wherein the asset remains with the private entity at the end of the contract period would not fall into the PPP category. However, BOO is classified as PPP by several literatures (Azarian et al, 2022, Cheng et al., 2019; Grimsey & Lewis, 2004;). Additionally, legislation in various countries including Vietnam, the Philippines, India, Kenya, and Indonesia, also recognize BOO as a form of PPP. Therefore, in those countries, BOO model may benefit from state's financial incentives such as tax-exempt status (DPI HCMC PPP Division, 2017; Republic of the Philippines PPP Center, 2012; India Department of Economic Affairs, 2023; ADB, 2020).

From the perspective of asset ownerships, BOO arrangement that resembles privatization highlights contractual structure disadvantages for public entity (Akhtar, et al 2023 ; William, 2023). To address these disadvantage issues, the BOOT arrangement has therefore emerged that make the asset ownerships to public entity at the end of contractual period is possible (Akhtar, et al 2023).

Table 2: Public and private provision of infrastructure classified by the involvement of public and private sector (ADB, 2021; Yescombe, 2007).

	Strong public participation ←					→ Strong private participation
			← Public private partnership →			
Contract Type	**Public-sector procurement**	**Franchise *(Affermage)***	**Design – Build – Finance – Operate (DBFO)**	**Build – Transfer – Operate (BTO)**	**Build – Operate – Transfer (BOT)**	**Build – Own – Operate (BOO)**
Construction	Public sector	Public sector	Private sector	Private sector	Private sector	Private sector
Operation	Public sector	Private sector	Private sector	Private sector	Private sector	Private sector
Ownership	Public sector	Public sector	Public sector	Private sector during construction, the public sector	Private sector during the contract, then the public sector	Private sector
Who pays?	Public sector	Users	Public sector or users	Public sector or users	Public sector or users	Private sector off-taker, public sector, or users
Who is paid?	n/a	Private sector	Private sector	Private sector	Private sector	Private sector

1.2 Potential benefits of PPP

While a range of diverse potential positive outcome promises have been made in the context of reforms leading to PPP implementation, its fiscal and financial benefits are consistently mentioned (Alfen, 2009; Estache, 2006; Liu & Love, 2014; Than Nguyen et al. 2020; Yurdakul et al., 2022). The expected fiscal benefits of reforming to PPP, especially in the short term, were often seen as PPP's main advantage. The anticipated gains came from three sources: (i) income from asset sales, leases, or rentals; (ii) reduced public sector operational and capital expenditures due to shifting responsibilities to private operators; and (iii) a net increase in tax and non-tax revenues (Estache, 2006). However, this has to be considered very carefully, and several studies challenged this view. Engel et al. (2020) argued that, independently of the type of procurement, whether it is PPP or traditional procurement, the fiscal impact of a project in present value is the same. For example, in the case of a toll road project, the government may initially save by not having to pay upfront for the construction. But, subsequently, these savings are equal to the toll revenues that will go to the hands of private partners during the duration of the PPP contract. The study concluded that PPPs would be more credible if their effects on the intertemporal fiscal constraint were acknowledged, meaning investments in PPPs should be accounted for as public investments in public accounts, given their equivalent effect on the intertemporal fiscal constraint.

Literature suggests vast potential benefits of PPP other than the fiscal benefit discussed above. The PPP concept has been widely proposed to overcome the public sector's limitations as it is believed that it has many advantages, such as potentially using the private sector's resources, stirring up innovation, improving productivity, providing better risk allocation, promoting value for money and delivering cost-effectiveness (Ng et al., 2012). These benefits reveal the main objective and justification, which is the economic case of PPP: efficiency gain (Engel et al., 2020). Most governments are drawing their decisions for PPP based on the greater efficiency the private promoter delivers compared to traditional public procurement (Alfen et al., 2009). PPP comes with the promise of higher productive efficiency, a possible trade-off between productive and allocative efficiency, and higher costs, some of which are real resource costs to society, others not (Valila, 2020).

The following section discusses further the potential advantages of PPP based on a wide number of literature (Alfen et al., 2009; Engel et al, 2020; Estache, 2006; Saussier & de Brux, 2018; Valila, 2020):

1. **Leveraging the expertise and experience of private sector:** Private sector often offer extensive expertise and experience, which the public sector may lack of. This includes better management techniques, latest technology adoptions, and optimized solutions that can significantly enhance the effectiveness and efficiency of public services. This expertise is critical in complex projects where specialized knowledge significantly influences outcomes. Further, creating a Special Purpose Vehicle (SPV) for PPP execution allows a clearly defined scope and dedicated management team that reports to the firm's board.
2. **Introducing competition:** Traditionally, the public sector lacks market pressure that drives efficiency and innovation. By opening the public sector to private participation, it encourages companies to compete for obtaining contracts through offering better values, solutions, and service delivery. The competition can benefit the public, as it can lead to higher quality service at lower costs.
3. **Innovation**: The private sector's drive for profit and competitive advantage fosters innovation. In a PPP model, this can translate into innovative ways of managing public services that improve quality, efficiency, and user satisfaction. Innovation can range from new technological implementations to advanced management practices that streamline operations and reduce costs.
4. **Risk sharing:** PPP allows the distribution of risks between public entities to private operators, such as production risks, demand-related risks, and operating costs, according to which party can manage them best. This optimal risk allocation leads to better project management and lower life-cycle costs, hence higher efficiency. In some cases, private operators, with their broader range of activities and risk management expertise, can diversify and handle these risks more effectively than public organizations. In other cases, risk sharing can attract private investment to sectors where risk is a significant barrier. In summary, the ideal level of risk-sharing depends on several factors: how much risk the private contractor is willing to take on, the costs they incur to manage these risks, and the relationship between their unobserved efforts and the results that can be seen.
5. **Restructuring public sector services:** by embracing private sector capital and practices, reducing political interference. PPPs allow public sector services to be restructured by leveraging the operational expertise of the private sector, potentially leading to efficiency and better service quality. Additionally, minimizing political interference can result in more stable and predictable project management, allowing to building of an environment where long-term planning and strategic making is possible (Hodge & Greve, 2007). In the concession model, PPP enables users to pay the firm responsible for building and operating the infrastructure asset directly, thereby eliminating the inefficiency costs associated with government bureaucracy.
6. **Project bundling minimizes total life-cycle cost**: The reasoning is that because the concessionaire will operate and maintain the project, it will design and build the project to minimize life-cycle costs. Moreover, if there is strict monitoring of compliance with the conservation standards, it is in the concessionaire's interest to design and build the project to maintain the infrastructure at minimum life-cycle costs.
7. **Economic of scale:** Private partners in PPP are often specialists who serve multiple customers in the same business, allowing them to reduce average costs and pass these savings through competitive pricing. This particularly applies when substantial fixed costs must be spread over large production volumes. Thus, this benefit only applies in conditions where the assets involved are very specialized or if the public entity retains a monopoly.

2. PPP IN DEVELOPING COUNTRIES

2.1 Overview

PPP has been practiced and utilized extensively around the globe for some time now, in both developing and developed countries (Osei-Kyei and Chan, 2017; Abdel Aziz, 2007). According to Fabre & Straub (2023), in

terms of their contribution to investments in physical and social infrastructure, estimates indicate that PPPs represent approximately 3 percent of global infrastructure spending. In addition, a number of PPPs attract a significant share of public financing, both directly or indirectly, through guarantees. PPP is, globally, seen as a valuable tool for mobilizing private sector resources and addressing infrastructure gaps. Several multilateral development institutions, including the World Bank, Asian Development Bank, Inter-American Development Bank, and European Bank for Reconstruction and Development, have drawn strategic directions to better support PPP, including institutional arrangements, product offerings, focused interventions, and knowledge management. Further highlighting PPP's importance globally to foster development, PPP is also explicitly mentioned in the United Nations 2030 Agenda for Sustainable Development, specifically under Sustainable Development Goal 17: Strengthen the means of implementation and revitalize the Global Partnership for Sustainable Development (UN, 2015) Lately, the implementation of PPP financing model is also extended to de-risk high risk projects particularly in developing countries (Sastoque et al, 2024 ;). PPP financing model provides a partnerships framework to incentivize the essential projects that can reduce the risks and project costs borne by private partners (Hou et al, 2024).

While there has been a long history of private sector provision of public goods and services, the PPP model has re-emerged in developed economies since the beginning of the 1990s and even earlier in the 1980s (Grimsey & Lewis, 2004; Vining et al, 2004; Zwalf, 2020). However, PPP started to be used in developing countries much later than that. For example, Wang et al. (2022) observed that the Chinese government began to promote PPP projects only in 2014. Another emerging economy, Brazil, started to see PPP projects become a reality only in 2007, even though it has enacted the PPP Law since 2004 (Barral & Haas, 2007). India started earlier by marking the onset of several PPP projects in the transport and power sector in mid-1990 (Sharma et al., 2021); however, it was only in 2004 that India formed an infrastructure committee to promote and supervise PPP policies formulations and project implementations (Cheng et al, 2019). Within a similar timeframe to others, Indonesia starts to develop PPP after decentralization reform in the 2000s (Yaya, 2014).

According to data from the World Bank (2024), as shown in Figure 1, 2023 saw total private sector commitments in infrastructure (including all types of private sector investments from PPP to full privatization) in low- and medium-income countries reached US$ 86 billion, indicating a bounce back after a significant drop in private sector investments in infrastructure following Covid 19 pandemic. However, this is merely equivalent to 0.2% of these countries' GDP. This amount is also very far from the average infrastructure investment required in those countries, which is estimated at US$ 1.5 trillion per year (Rozenberg & Fay, 2019).

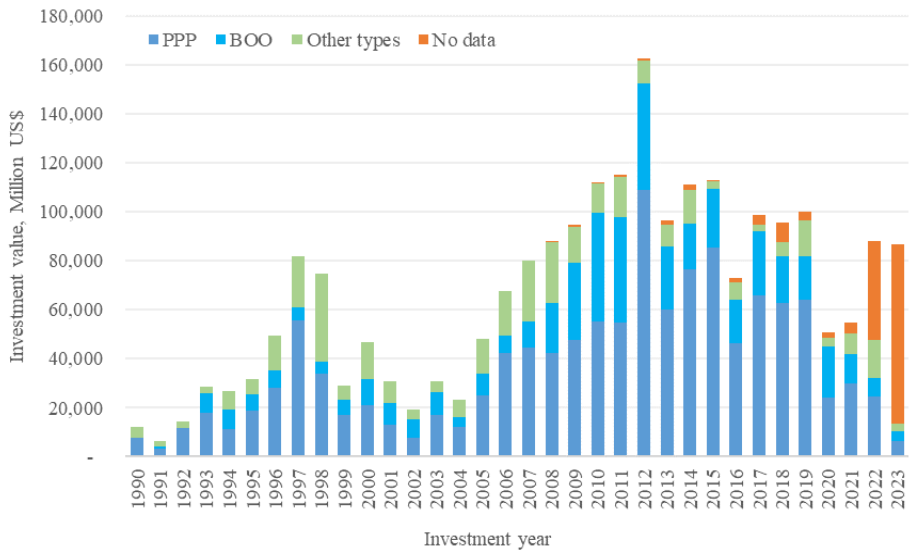

Figure 1: Private Investment in Infrastructure Projects, including PPP (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-Operate-Transfer, and Build-Operate-Transfer), Build-Own-Operate, Other Types (Lease contract, Merchant, Rental, etc.), and Projects with No Data, in Low and Mid-Income Countries, 1990-2023 (data from The World Bank, 2024).

In recent years, data from the World Bank Private Participation in Infrastructure indicated well how much of the total private investments could be categorized as PPP (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-Operate-Transfer, and Build-Operate-Transfer). Between 1999 and 2021, on average, 56% of total private investments could be classified as PPP. However, it is important to note that the majority of private investment types in 2022-2023 were not categorized (no data), and only a small proportion were clearly classified

as PPP categories. This does not necessarily mean that PPP investment dropped significantly, as the investment types are not clearly categorized.

2.2 PPP in Energy Sector of Developing Countries

Governments usually use PPP for economic infrastructure, such as energy, electricity, roads, airports, ports, railways transport, or social infrastructure, includes education, health, water and sanitation and urban or rural development (Grimsey & Lewis, 2004). In industrialized countries, PPPs are used in areas of public service provision including education, health services, waste management and public buildings. In the other side, in developing countries with enormous needs for basic infrastructure, PPPs are often seen in the power, water, or road sectors in order to sustain the countries' rapid economic growth (Alfen et al., 2019).

PPP in the power generation sector is typically established to develop a specified amount of power capacity or a particular project. The power purchase agreement (PPA) and/or concession agreement outline the obligations, benefits, and risk allocations. In a standard PPP for power generation, private investors construct a power plant and agree to sell the electricity produced to a publicly owned utility. The public authority assumes the demand risk by guaranteeing a minimum payment for the plant's availability or capacity, regardless of whether its output is needed. Additionally, a usage payment is made to cover the fuel costs for the plant. (ESMAP, 2012)

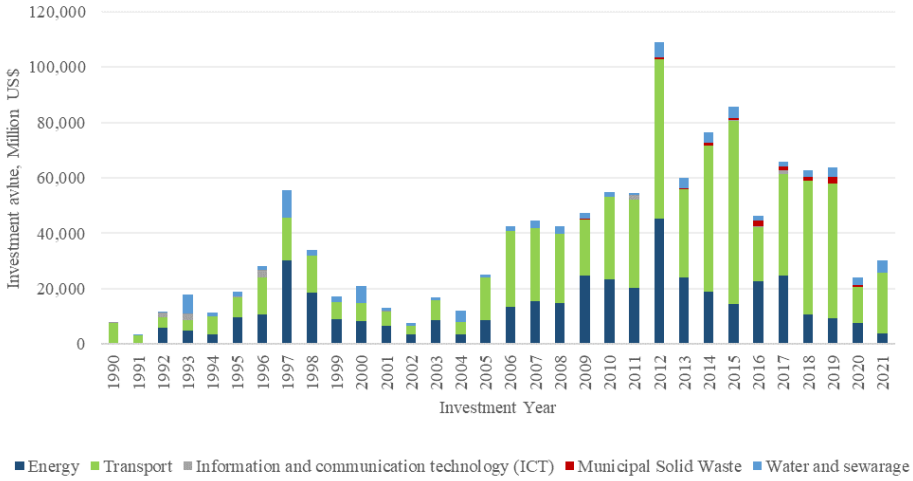

Figure 2: Investment Values of PPP Projects (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-Operate-Transfer, and Build-Operate-Transfer) by Sector, in Low and Mid-Income Countries, 1990-2021 (data from The World Bank, 2024).

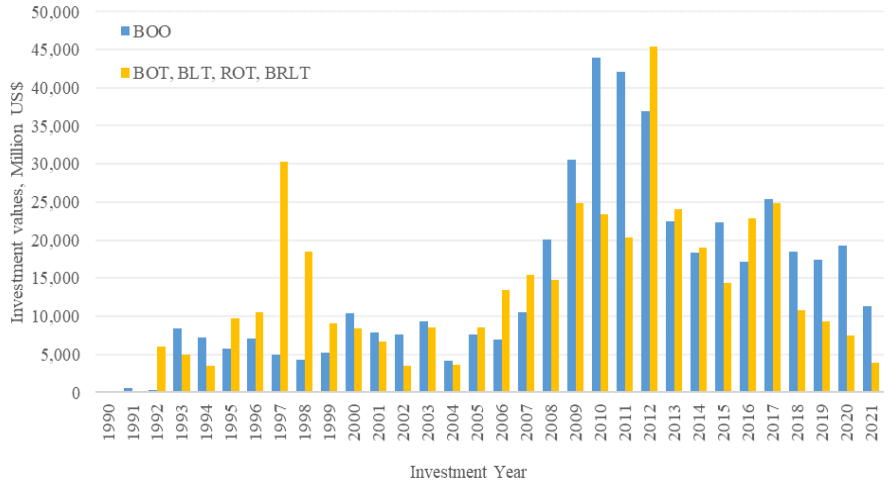

Figure 3: Investment Values of BOO Projects in Energy Sector compared to PPP Projects (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-Operate-Transfer, and Build-Operate-Transfer) in Energy Sector, in Low- and Mid-Income Countries, 1990-2021 (data from The World Bank, 2024).

Indeed, data extracted from the World Bank PPI database shows that, over the period from 1990 to 2021, nearly 90% of investments in PPP projects (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-

Operate-Transfer, and Build-Operate-Transfer) in low and middle-income countries were predominantly in the transport and energy sectors. Over those years, in average, investment in energy sector represents 36% of all PPP investments. As a note, in this dataset, transport sector consists of airport, road, port, and railway, while energy sector consists of electricity generation, transmission, distribution, natural gas transmission and distribution. The third largest sector is water and sewerage sector, but the average share, by far, only represents 9% of total investment (Figure 2). Authors do not include the numbers of PPP investments in year 2022-2023 because of the inadequacy of accurate categorization, as mentioned in section 2.1 above.

An interesting aspect of energy projects is that many were executed using the Build-Operate-Own (BOO) model, which is classified as PPP by several institutions, including the Indonesian government (see section 1.1). Figure 3 illustrates that the BOO model is widely used in energy projects, with total investment values slightly higher (6% larger) than all other PPP models combined over the years. In fact, more than 93% of BOO projects in The World Bank's database from 1990-2021 are in the energy sector. More importantly, the bulk of those projects (75%) are in electricity generation.

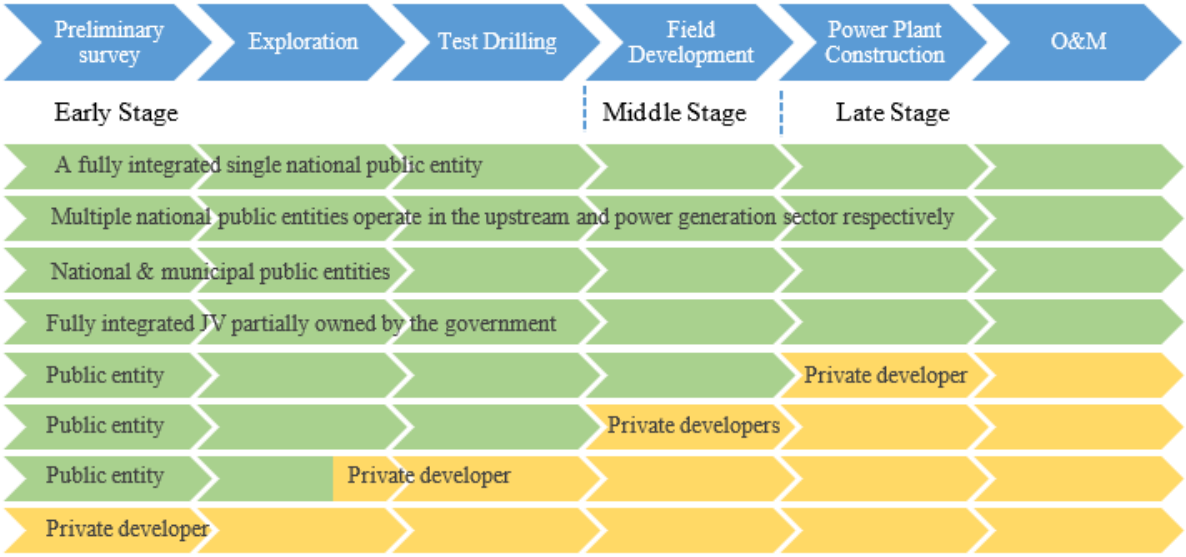

Figure 4: Models of Geothermal Power Development in International Practice (based on ESMAP, 2012)

3. PPP IN GEOTHERMAL KENYA, TÜRKIYE, AND THE US

Geothermal energy is the energy contained as heat in the earth's interior. For decades, natural steam and hot water from geothermal sources have been used to generate electricity, as well as for space heating and industrial processes (Barbier, 2002). The discussions forward exclusively refer to geothermal for power generation, unless otherwise specified.

By the end of 2023, the global geothermal capacity has reached 16,355 MW. The top 10 geothermal countries are the **United State**s (3,900 MW), **Indonesia** (2,418 MW), **Philippines** (1,952 MW), **Türkiye** (1,691 MW), **New Zealand** (1,042 MW), **Kenya** (985 MW), **Mexico** (976 MW), Italy (916 MW), **Iceland** (754 MW), and **Japan** (576 MW). Those countries represent 93% of total installed capacity globally. Note that different calculation methods can affect the total reported capacity, resulting in variations in the numbers presented by different countries and organizations (Cariaga, 2024).

Although geothermal is unique amongst other renewable energy sources as it provides baseload power, adopting geothermal energy has lagged significantly behind solar and wind. While many of the risks involved in geothermal projects are similar to other power or electricity generation projects, including: completion or delay risk, off-take risk, market demand or price risk, as well as operational and regulatory risks, they also involve additional complexities. Those are mainly attributable to (i) uncertainties over resource availability in poorly-explored reservoirs and (ii) the concentration of full-lifetime costs into early-stage capital expenditure (capex). The early stage of geothermal projects is subject to a high degree of unpredictability, with the risk involved decreasing progressively as investments advance (Nur et al., 2023; Younger, 2015).

The initial phases of greenfield geothermal project development (surface-based exploration, discovery, and exploration drilling to confirm the availability and viability of the resource) carry the highest risks and require financial investments. Private parties are often unwilling to invest at this stage due to the potential for

inadequate/unviable resource findings, resulting in substantial sunk costs that cannot be recovered. Test drilling alone can account for up to 15% of the overall capital cost. Therefore, one of the main issues for countries to develop geothermal resources is similar: the ability of the private sector to take on the high risks associated with the exploration and development of geothermal resources. Indeed, these early phases typically depend on public sector investment, while private investors tend to enter the project at more mature phases (Nyokabi et al, 2023; Oliver & Stadelmann, 2015).

In the next sections we will go through the overview geothermal development in select top geothermal countries, the financing mechanism to develop geothermal in each country, including PPP, as well as the electricity market which form the downstream segment of geothermal power industry.

3.1 Geothermal in Kenya

3.1.1 Overview

Kenya, an East African nation, is particularly notable for its renewable energy development. In 2021, around 90% of its total electricity generation are from renewable sources. Further, geothermal constitutes the largest share of the total renewable electricity at 45%, and the rests come from hydro (33%), wind (18%), and a little bit from solar and biofuel (IEA, 2024a).

Kenya can be considered one of the most advanced African electricity markets in terms of policy and regulatory effectiveness. Since the 1990s, the governance of its power sector has continuously evolved to reflect market fundamentals, ensure reliable electricity for its growing economy as well as to attract new investments, improve competition, and progressively open the electricity market. In 1997, the government has unbundled the electricity subsectors to enhance efficiency, with KenGen (Kenya Electricity Generating Company) mandated to generate power and KPLC (Kenya Power and Lighting Company) mandated to transmit and distribute power. Since then, geothermal power developed by the public sector, through KenGen, has increased from 45 MWe in 1997 to 706 MWe in 2019 (IRENA, 2020). Further, the 2019 Energy Act liberalized the electricity supply industry, opening private sector participation in generation, transmission, distribution, and off-grid. Another decisive step in attracting private sector investments has been the 2021 Public-Private Partnership Bill, which established a framework for public-private cooperation in infrastructure and services (UNECA, 2022). Electricity pricing is determined by the Energy and Petroleum Regulatory Authority (EPRA), which sets tariffs for residential and commercial consumers and determines the prices for electricity generated. Electricity prices are set with the aim of attaining sufficient revenue to meet generation, transmission, and distribution requirements, reflective of the cost of power generation, which forms the base, pass-through charges, system losses, taxes, and levies (KIPPRA, 2023)

Geothermal development in Kenya started in the Olkaria field in the 80s with 45 MW capacity and only restarted again in the same field in the year 2000 to total 58 W capacity (Omenda et al., 2023). At the end of 2023, Kenya has an installed geothermal capacity of 985 MW, an impressive increase of 24-fold over 24 years. There are three geothermal fields in operation in Kenya by the beginning of 2024: **Olkaria field** (where 99% of the geothermal electricity is generated), **Eburru field**, and **Menengai field**. The government is targeting installed generation of 5,000 MW by 2030, with additional capacity from Olkaria and Eburru field (Gutiérrez-Negrín, 2024)

3.1.2 Financing geothermal, including PPP, in Kenya

Financing of geothermal projects in Kenya has relied on private, public and grant financing. Public finance was used for most of the early stages of geothermal exploration in Kenya through government-owned companies: KenGen (Kenya Electricity Generating Company) and GDC (Geothermal Development Company). GDC was established to accelerate geothermal development by derisking geothermal projects through the undertaking the early stage of geothermal development. It channels funding from exchequer and concessionary finance guaranteed by the government (Kiptanui & Kipyego, 2021; Omenda et al, 2023). The cumulative government financial support for the two institutions was more than USD 5 billion between 2003 and 2016. Most of the financial support to GDC was for resource evaluation, exploration, appraisal and production drilling while concessionary loans lent to KenGen were for power plant developments (IRENA, 2020).

All the successful projects so far in Kenya are those that benefitted from public financing at some stage of their development:

- Public finance was used in all the successful projects starting with the development of **Olkaria's 45 MWe, Olkaria II, Olkaria IV, Olkaria V and Olkaria I Units 4, 5, 6** projects developed by KenGen through concessionary finance. Whereas **Olkaria III** project is being undertaken by private investor, the initial stages from surface exploration to appraisal drilling was undertaken by KenGen through public finance before the field was licensed to Orpower4 Inc. by the Government of Kenya through PPP arrangement. Subsequent projects that include production drilling, steam field and power plant development were financed by the IPP (Independent Power Producer) through equity and loans.

- In **Menengai field**, GDC undertook exploration, appraisal and production drilling, steam field development and has then entered into a steam sales agreement with three IPPs for the development of 105 MWe. GDC will be steam supplier while the IPPs will use private finance to setup the power plants and enter into PPAs with off-taker.

The Government of Kenya also recently licensed IPPs to explore and develop geothermal resources for power generation using their own financial resources. Only Akiira and Barrier geothermal prospects are the only ones so far funded by private investors for exploration drilling and detailed surface studies, respectively (Omenda et al., 2023).

According to the Kenya Public Partnership Act No. 14/2021, the PPP arrangements recognized several models including the most common schemes such as BOOT (Build-Own-Operate-Transfer), BOO (Build-Own-Operate), BOT (Build-Own-Transfer), and BLT (Build-Lease-Transfer) (PPP Directorate, 2021). Table 3 shows the list of PPP models of several geothermal projects in Kenya.

Table 3: PPP Models of Several Geothermal Projects in Kenya (Kiptanui & Kipyego, 2021; Nyokabi, 2020; Richter, 2020).

No	Project	Contracting Authority	PPP Model
1	155 MWe Olkaria III	Gov. Kenya	BOO
2	35 MWe Sosian Menengai Geothermal Power Plant Project	GDC	BOO
3	35 MWe QPEA GT Menengai Geothermal Power Plant Project	GDC	BOO
4	35 MWe OrPower 22 Menengai Geothermal Power Plant Project	GDC	BOO
5	140 MWe Olkaria VI	KenGen	BOOT

3.2 Geothermal in Türkiye

3.2.1 Overview

Türkiye has garnered attention for its impressive geothermal power capacity's growth, which has increased tremendously from just 20 MW in 2005 to more than 1.6 GW by the end of 2023 (Gutiérrez-Negrín, 2024; Cariaga, 2024). Besides its gigawatt geothermal capacity for electricity generation, Türkiye is also the world's second-largest user of geothermal heating, surpassed only by China (Mertoğlu et al., 2020).

Türkiye has liberalized the electricity sector to a good extent. Both public and private companies, as well as organized industrial zones, can generate electricity with a license from the Energy Market Regulation Authority (EMRA). Transmission remains a state monopoly through Turkish Electricity Transmission Company (TEİAŞ). In 2013, a new type of market was introduced under the Electricity Market Law, leading to the establishment of EPİAŞ. This entity, jointly owned by TEİAŞ, Borsa Istanbul, and private companies, responsible for the operations of energy market and is tasked with operating the day-ahead market, the intraday market, and the newly created YEK-G green certificate market. In the downstream side, electricity distribution and supply are legally unbundled, operated, and carried out by both private and public companies (Somay et al, 2021; PwC, 2023).

3.2.2 Financing geothermal, including PPP, in Türkiye

Although geothermal research and investigations in Türkiye have been ongoing since the 1960s, and in 1984 Europe's second largest geothermal plant (after Italy) was constructed at Denizli-Kizildere, the country's geothermal power generation activities progressed very slowly thereafter (Tut Haklidir, 2015). According to study by Korucan et al. (2024), the critical milestones that accelerated geothermal developments in Türkiye were (1) the adoption of the Law on Geothermal Resources and Natural Mineral Waters in 2007 which set the rules for the exploration and exploitation of geothermal resources, and (2) the amendment in 2010 to Renewable Energy Law offering a feed-in tariff mechanism (*YEKDEM*) that was 105 US$/MWh and for ten years from the commissioning date. Additional incentives were also provided to the plants for their locally produced equipment, up to 27 US$/MWh for 5-year period.

Aside from the feed-in tariff, there is a Risk Sharing Mechanism (RSM) funded by the World Bank, established in 2016. The RSM program assesses the location of the planned project site, providing grants that cover either 40% or 60% of the well's cost, depending on the site's rating (Saltuk et al., 2023). Given that geothermal development in Türkiye relies heavily on the private sector, the RSM supports investors during the riskiest development stages. This is crucial as private license holders must bear full exploration risks in areas with minimal or no government backing. Historically, geothermal development in Türkiye was driven by the General Directorate of Mineral Research and Exploration (MTA). MTA has started geothermal exploration since 1962, discovered over 190 geothermal fields, of which around 20 were deemed suitable for electricity production.

However, its capacity for extensive geothermal exploration drilling has diminished, significantly slowing exploration activities and leaving potential regions remain largely unexplored. RSM reduced private investors' exposures to significant capital expenditures and exploration risks in the early development phases (The World Bank, 2016).

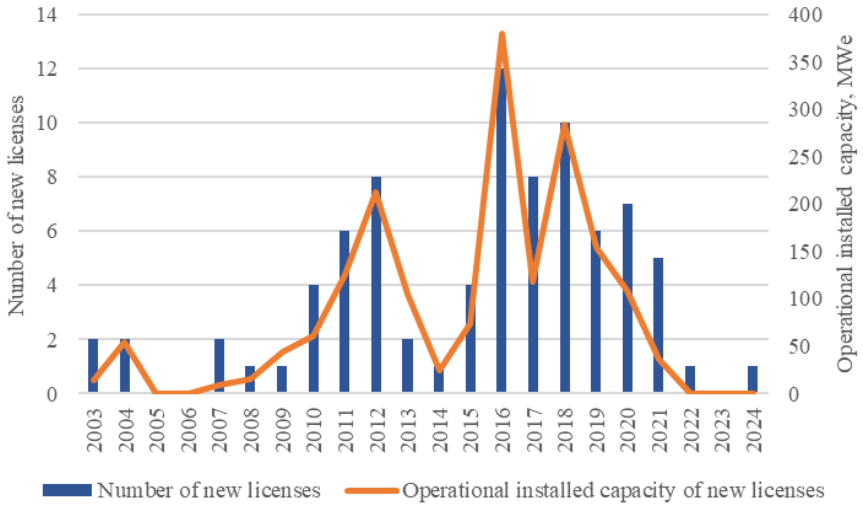

Figure 5: Number of new licenses and their installed capacity in Türkiye, 2003-2024 (based on data by Korucan et al., 2024).

With those mechanisms, the geothermal market became very attractive for investors, even those from non-energy sectors such as construction, textile, and real-estate. However, after 2021, as can be seen in Figure 5. Number of new licenses and their installed capacity in Türkiye, 2003-2024 (based on data by Korucan et al., 2024)the geothermal growth has stalled. Among many issues observed, the change in the YEKDEM mechanism in 2021, which switched incentives from USD to Turkish Lira, was a significant obstacle to new investments. Due to the depreciation of the domestic currency against USD, the incentives are not any more attractive and discouraging investment. On the other hand, the costs related to the feed-in tariff system are reflected in the invoices that people regularly pay. Therefore, the devaluating Turkish Lira was a part of the main reasons for the clash of interests among the renewable energy investors, the state, the people, and other relevant actors (Can Sever, 2021; Korucan et al., 2024). To address these issues, YEKDEM was recently updated in May 2023, and the results will be seen in the succeeding years. The new regulation retains the Turkish Lira for the application price in the support scheme but also introduces monthly US$-indexed adjustment. The system also includes an escalation process by adopting the floor and ceiling price principles in payments (Cariaga, 2023).

PPP in geothermal is not widely discussed in Türkiye. One notable PPP case is Gümüşköy Geothermal Project, developed a Build-Own-Transfer scheme. The private partner, BM Holding, undertook early-stage exploration and invested up to US$ 12 M in exploration and development, when finally debt financing, 70% of the total cost, was secured. The Government of Turkey's provision of a ten-year feed-in tariff (10.5 USD¢/kWh) ensured the project was financially viable (Oliver & Stadelmann, 2015).

According to the World Bank PPFI database (2024), there are only five PPP geothermal projects (Build-Lease-Transfer, Build-Rehabilitate-Operate-Transfer, Rehabilitate-Operate-Transfer, and Build-Operate-Transfer) listed in Türkiye from 1990-2023 and all are brownfield projects: Zorlu Kizildere projects. There is only one is greenfield project, Efeler Geothermal Project (170 MW, year 2015) which was executed in BOO scheme.

3.3 Geothermal in the United States of America

3.3.1 Overview

The United States (US) remains the leader in installed geothermal capacity for power generation with nearly 4 GW of electricity-generating capacity installed, representing around 24% of the world's total capacity. More than 90% of the U.S. geothermal capacity is in the states of California and Nevada. Beside geothermal for electricity, the US also has 20.7 GW_{th} installed geothermal capacity for direct use (IEA Geothermal, 2024). The capacity growth in the past decade is only approximately 10%, as the addition of new plants has been offset by the retirement or decommissioning of others. The GeoVision study, initiated by US Department of Energy, sees that with business as usual scenario and using current technology, geothermal capacity in the US can grow to 6 GW in 2050, but with regulatory reform this can reach 13 GW. The GeoVision TI scenario, which models the most optimistic assumptions and cost reductions, indicates significant potential for geothermal deployment, especially

for Enhanced Geothermal Systems (EGS) resources. The scenario projects more than 60 GW of geothermal power generation after 2030, with a substantial portion coming from deep-EGS resources (US Department of Energy, 2019).

Electric utilities in the United States operate under a variety of market structures, depending upon the states in which they operate. Some states adopt deregulation/restructuring, allowing market competition for retail energy supply to electricity customers. Utilities in deregulated markets are prohibited from generation and transmission ownership and are only responsible for distribution, operations, maintenance from the point of grid interconnection to the meter, and billing ratepayers. On the other hand, regulated markets feature vertically integrated utilities that own or control the total flow of electricity from generation to meter (US Environmental Protection Agency, 2024). Around 30% of US states are deregulated, including some of the most populous such as California, Texas, New York, and Pennsylvania, but not Florida (American Public Power Association, 2021). In deregulated areas, electricity customers have the option of selecting an electric supplier rather than being required to purchase electricity from their local electric utility. This introduces competition for retail electricity prices. Some states also support geothermal development by enforcing Renewable Portfolio Standard, by requiring a certain amount of electricity sold by utilities to come from renewable energy sources (NREL, 2021).

Geothermal operators typically sell electricity through power purchase agreements (PPA) which provide long-term financial stability, but also to the wholesale markets which include day-ahead and real-time markets.

Table 4: Public Geothermal PPA Pricing (NREL 2024).

Project	State	Size (MW)	Pricing (US$/MWh)	Term (years)
Hell's Kitchen	California	40	74.00	25
Whitegrass	Nevada	3	67.50	25
Star Peak	Nevada	125	70.25	25
Casa Diablo	California	16	68.00	20
Puna	Hawaii	46	70.00	30

3.3.2 Financing geothermal in the US

In the US, geothermal projects are predominantly developed through private investments. Nevertheless, there are several mechanism to support geothermal developments over the year, with the followings, among others, currently in place (NREL, 2021):

- **Tax-Based Incentives:** Investment Tax Credit (ITC) offers up to 30% of qualifying capital cost in tax credits and Production Tax Credit (PTC) offers tax credit proportional to power plant's electricity generation (adjusted annually for inflation, PTC was 2.5 cents per kWh in May 2020).
- **Cash Grant (1603 Grant):** in 2009, the government allowed geothermal developer to claim 30% cash grant in lieu of the PTC. However, this grant closed for application in 2011.
- **Depreciation Acceleration & Bonus Depreciation:** the depreciation acceleration scheme allows geothermal projects for a 5-year depreciation schedule, therefore the operators can use the total depreciation value of the asset for tax deduction sooner. The bonus depreciation allows geothermal companies to deduct between 50-100% of their qualifying assets in the first year of the operation.
- **Federal Funding and Grants:** Through Energy Act 2020, DOE is authorizes annual budget authorized at $170 million for research and development activities, including advanced hydrothermal resource tools, demonstration projects, oil and gas, technology transfer, and co-production of geothermal energy and minerals.
- DOE also initiated **User-Coupled Confirmation Drilling Program (UCDP)** designed to financially assist geothermal power developers in the initial stages of confirming hydrothermal reservoirs. UCDP takes 20% of the cost if the project was successful in the confirmation of geothermal resources, and 90% from UCDP if not, with limited fund of US$ 3 M per application.
- **State level incentives:** vary widely among states with the following examples: in Nevada, owners of geothermal power systems of at least 10-MW capacity are eligible for a 55% property tax abatement for 20 years. Alaska offers Renewable Energy Fund Grant, which includes geothermal, values up to US$ 2 M per project.

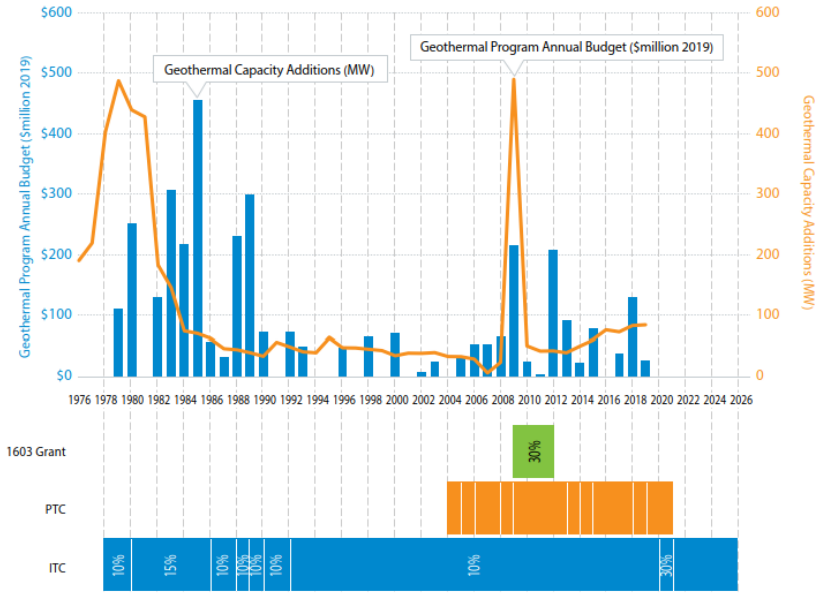

Figure 6:Timeline showing annual data for federal fundings for geothermal program (1603 Grant, PTC, ITC) and geothermal capacity addition (NREL, 2021).

4. GEOTHERMAL IN INDONESIA

4.1 Overview

Indonesia holds approximately 40% of global geothermal potential or 23.7 GW, with the largest potentials lie in the islands of Java and Sumatra (Indonesia Ministry of Energy and Mineral Resources, 2024). Nevertheless, in 2021, geothermal energy only represents 5.2 % of Indonesia's electricity mix (IEA, 2024b). By the end of 2023, the total geothermal installed capacity in the country is 2.4 GW or only around 10% of the total potential. The Government of Indonesia initially aimed to achieve a geothermal installed capacity of 7.2 GW by 2025. However, due to slow progress, this target was revised to 2030 (Hakim, 2023).

4.2 Financing geothermal in Indonesia

Currently, there are more than 8 geothermal operators in Indonesia, three of them are state-owned: Pertamina Geothermal Energy (PGE), Perusahaan Listrik Negara (PLN; the state electricity company), and Geo Dipa Energi. Operators are responsible to undertake and finance the total project, i.e. starting from the very early project stage (initial survey and/or exploration), development, until power plant construction, to operation and maintenance.

To mitigate the risks associated with early project development, the government is undertaking government exploration drilling through MEMR. As of May 2024, the Nage field in East Nusa Tenggara is the only site successfully explored under the government drilling scheme and ready for tender. Additionally, since 2019, the Geothermal Resource Risk Mitigation (GREM) program offers loans with a provision for 50% forgiveness if the exploration drilling results deem the resource uneconomic. The total commitment of GREM funding is USD 651.25 million which comes from a combination of multilateral funds (International Bank for Reconstruction and Development, Green Climate Fund, Clean Technology Fund) and Geothermal Sector Infrastructure Development (*Pembiayaan Infrastruktur Sektor Panas Bumi*, PISP) funds. However, by early 2024, no geothermal operator has yet utilized the GREM fund (Amir et al., 2024; Cariaga, 2024b; Indonesia MEMR, 2020; PT SMI, 2024).

Indonesia is a single-buyer electricity market, where the state, through the National Electricity Company (Perusahaan Listrik Negara, PLN), buys all the electricity generated in the country and resells it to the electricity consumers at regulated price. Indonesian regulations do not allow independent power producer (IPP) to enter into direct power purchase agreement (PPA) with customers. This limits the ability of consumers to procure power produced from renewable sources directly. This is especially true for commercial and industrial consumers who are increasingly setting ambitious clean energy procurement targets (WEF, 2022). The private sectors can only participate in electricity generation as IPP with a PPA in place for performance-based payments from the public sector party over a long-term concession period. This PPA structure is consistent with the general principles of PPPs. (Atmo et al., 2016). Accordingly, IPPs in a single buyer market models have been classified as PPP power generation projects (Voelker et al., 2008). Previously, the PPP model for renewable energy is limited to Build-Own-Operate-Transfer (BOOT) scheme, but with the Indonesia MEMR Regulation 4/2020, Build-Own-Operate

(BOO) model is allowed (Indonesia MEMR, 2020). This revision was based on the difficulties for private developers in terms of land ownership and the ability to obtain finance with the BOOT scheme.

The Government of Indonesia does not set a feed-in tariff for electricity for renewable energy, but sets highest benchmark price for electricity from renewable energy through Presidential Regulation 112/2022. The values depends on the source of energy, plant capacity, and is adjusted for each region (Table 5 and Table 6).

Table 5: Electricity from Geothermal Buying Price based on Presidential Regulation 112/2022.

No	Capacity	Highest Benchmark Price (cent USD/kWh)	
		Year 1-10 (F= location factor)	Year 11-30
1.	Up to 10 MW	9.76 x F	8.30
2.	>10 MW to 50 MW	9.41 x F	8.00
3.	50 MW to 100 MW	8.64 x F	7.35
4.	> 100 MW	7.65 x F	6.50

Table 6: Electricity Price Location Factor (F) based on Presidential Regulation 112/2022.

No	Region	Location Factor (F)
1	Java, Madura, Bali	1.00
	Small islands	1.10
2	Sumatra	1.10
	Riau Archipelago & Mentawai	1.20
	Bangka Belitung	1.10
	Small islands	1.15
3	Kalimantan	1.10
	Small islands	1.15
4	Sulawesi	1.10
	Small islands	1.10
5	Nusa Tenggara	1.20
	Small islands	1.25
6	South Maluku and Maluku	1.25
	Small Islands	1.30
7	Papua, including West Papua	1.50

4.3 PPP Frameworks and Institutional Setup in Indonesia

Indonesia's first official legislation on PPP, Presidential Decree 7/1998, focused on Government Cooperation with Private Business Entities in Infrastructure Development and/or Management, was specifically designed to stimulate private investment in infrastructure development following the monetary crisis (Permatasari et al., 2019). Since then, the government has made several efforts to enhance the attractiveness of PPPs by refining policies and regulatory frameworks, including updating the presidential decree with new regulations in 2015 (**Error! Reference source not found.**) and the most recent operational regulation relating PPP implementation i n Indonesia is stipulated in Indonesia Ministry of National Development Planning Regulation No. 7/2023 concerning Implementation of Government and Business Entity Cooperation in Infrastructure Provisions.

The policies developed over the years include several frameworks to support PPP implementations. Indonesia now has in place several government-support mechanisms (Indonesia Ministry of Finance, 2024; Indonesia Ministry of National Development Planning, 2023):

- **Project development facility (PDF)**: a facility provided by the Ministry of Finance to prepare pre-feasibility study, bidding documents, and assist in the PPP project transaction until it reaches the financial close.
- **Infrastructure guarantee facility**: this facility guarantees the financial obligations of a government contracting agency to compensate the project company in the event of infrastructure risks, as stipulated by the risk allocations agreed upon in the PPP agreement.
- **Viability gap fund (VGF)**: this government support, in the form of a contribution of some of the construction cost, given in cash to a PPP project that is already economically viable but has not had financial feasibility. VGF can be given when there is no other alternative to make the PPP Project financially feasible. It would only be given to infrastructure projects that are unable to deliver large

profits or with too long a turnaround time to attract investors to participate in the tender and does not include costs related to land acquisition and tax incentives

- **Land acquisition process**: One of the major impediments of PPP projects has been the land acquisition process. To address this, the government has issued revision of the land acquisition law under Presidential Regulation No. 148 of 2015. The law limits the land acquisition procedure to approximately 512 days and allows for the revocation of land rights in the public interest. To expedite the process further, the regulations enable private sector entities to acquire land on behalf of a government contracting agency and to seek subsequent reimbursement from the government. For example, in 2015, the Ministry of Finance established a bridging finance mechanism to facilitate the timely reimbursement of land acquisition costs to investors.

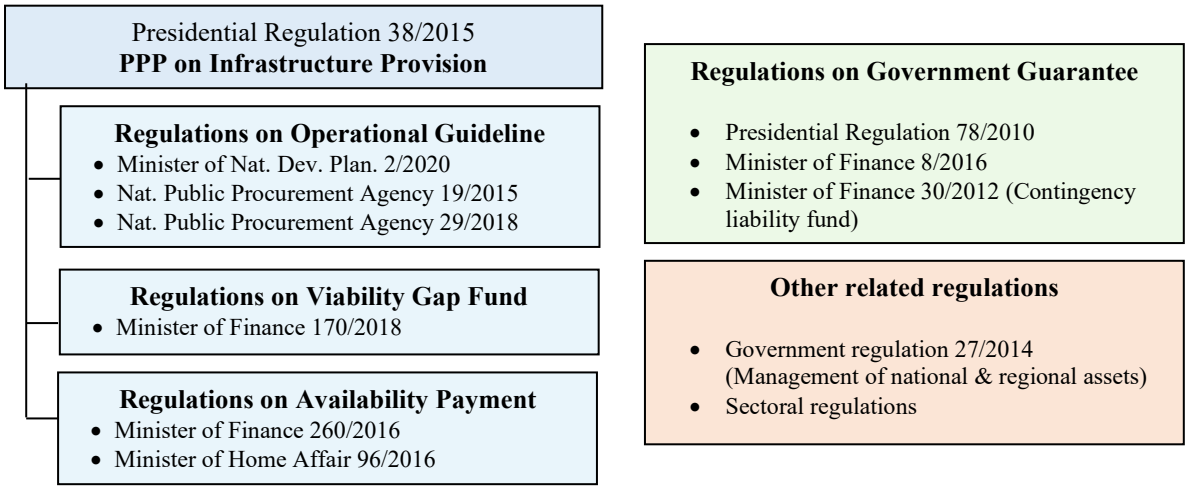

Figure 7: PPP Regulations in Indonesia (Indonesia Ministry of Finance, 2024).

According to Indonesia Ministry of National Development Planning (2023), PPP in Indonesia is driven by the following entities:

- the Ministry of National Development Planning/National Development Planning Agency/ Bappenas,
- the PPP Unit under the ministry of Finance, and
- the PPP Joint Office: formed in 2017 to accelerate the implementation of PPP, serving as central coordination body for those projects. The office consists of several ministries, including (1) Coordinating Ministry of Economic Affairs, (2) Coordinating Ministry of Maritime and Investment Affairs, (3) Ministry of Finance, (4) Ministry of Home Affairs, (5) Ministry of National Development Planning/National Development Planning Agency (Bappenas) (6) Ministry of Investment/Indonesia's Investment Coordinating Board (BKPM), and (7) National Public Procurement Agency (LKPP).

In addition, there are companies that play an active role in facilitating PPP (ADB, 2020):

- **Indonesia Infrastructure Guarantee Fund (IIGF)** or PT Penjaminan Infrastruktur Indonesia: a state-owned enterprise under the Ministry of Finance responsible for providing government guarantees for infrastructure projects developed under PPP,
- **PT Sarana Multi Infrastruktur (PT SMI)**: a special mission vehicle under the Ministry of Finance which is engaged in financing and preparing infrastructure projects,
- **PT Indonesia Infrastructure Finance (PT IFF)**, a private non-banking finance corporation providing infrastructure financing and advisory services, established by the Indonesia Ministry of Finance and other multi-/bi-lateral institutions. Ownership is shared by PT SMI (30%), Asian Development Bank (20%), IFC (20%), KfW (15.1%), and Sumitomo Mitsui Banking Corporation (14.9%).

Since 2009, the Ministry of National Development Planning/National Development Planning Agency/Bappenas annually publishes a document known as the "PPP Book", officially titled "PPP Infrastructure Projects Plan in Indonesia". It contains comprehensive updates on regulatory landscape, operational frameworks, and registered projects. Projects are divided into several groups based on the progress: ready-to-offer projects, projects currently under preparation, tendered projects, and a list of "success stories" or projects that are already closed financially.

Interestingly, the only power/electricity generation project listed in PPP Books, from all the years 2016 up to the latest in 2023, is the construction of Central Java Power Plant 2x1000 MW. Obviously, **there is no geothermal project listed in the registered PPP Projects**. It therefore means that geothermal projects currently do not benefit from the PPP supports provided by the government.

For eligible power projects in Indonesia, a different scheme is offered to address the concern on PLN creditworthiness and default risk: they are entitled to apply for Business Viability Guarantee Letter (BVGL) issued by Ministry of Finance (Rakhmadi and Sutiyono, 2015). In geothermal energy projects, Sarulla was the first project that received BVGL and followed by Muara Laboh, later on.

5. DISCUSSION AND RECOMMENDATIONS

The comparative analysis of geothermal public-private partnership (PPP) frameworks and cases from Kenya, Türkiye, and the United States reveals distinct approaches and outcomes in developing geothermal energy projects, providing valuable insights for Indonesia. The international cases in this study represent three countries with varying degrees of public and private involvements in developing geothermal projects:

- **Kenya** cases show projects with significant both public and private involvements, supported with well-institutionalized PPP schemes and frameworks in the country's regulations. Geothermal Development Company (GDC), as government arm, has played a crucial role in mitigating early-stage project risks, which has been instrumental in achieving a 24-fold increase in geothermal capacity over just two decades, nearing 1 GW installed capacity. The Kenyan model benefits from strong public financing at critical early stages, effectively derisking projects for private investors.
- **Türkiye** case highlights the importance of attractive feed-in tariff mechanism (YEKDEM), on top of a risk-sharing mechanism (RSM) to derisk the early riskiest stage of geothermal project. Public participations in the early and riskiest stage of the project through Directorate of Mineral Research and Exploration (MTA) also exist but recently decline and are compensated with RSM. Those combinations have catapulted Türkiye to stands out as one of countries with fastest growing geothermal capacity. However, in 2021, without significantly changing the model of public involvement, a change in feed-in tariff scheme had decreased the attractiveness of incentives and therefore reduced significantly the numbers of project being initiated. Türkiye government hence introduced a 2023 revision of the feed-in tariff mechanism to attract back private investments.
- **The United States** showcases very dominant private sector involvements in geothermal development, supported by various government supports including tax incentives and grants for early-stage exploration. This model underscores the importance of consistent government support throughout all project phases, contributing to steady geothermal development.

The empirical analysis of these international cases identifies several opportunities and recommendations for enhancing the effectiveness of PPPs in Indonesia's geothermal sector:

1. **Enhancing policy framework of risk-sharing mechanisms in the early stages of geothermal projects**
   Currently, the risks in the earliest stages of Indonesia's geothermal projects are borne solely by the operators. The existing derisking schemes, such as Government Drilling and the Geothermal Resource Risk Mechanism (GREM), are still in their infancy and have not yet been utilized by any operator. Indonesia can learn from Kenya, where the Geothermal Development Company (GDC), a dedicated public entity responsible for exploration activities, has been crucial for geothermal growth. Additionally, Indonesia can adopt the approach used in the US, where the government provides grants to share early-stage development risks instead of assigning a public entity for exploration.

2. **Enhancing policy frameworks to attract more investment by providing incentives and supports throughout all phases of geothermal projects**
   Turkey's case demonstrates that an attractive feed-in tariff significantly influences private sector participation in geothermal projects. In the US, the government offers innovative incentives across all project phases, both at federal and state levels. These include grants during the exploration phase, various tax incentives, attractive depreciation schemes, and funding for research and development (R&D). Implementing similar comprehensive support structures in Indonesia could attract more private investment in geothermal projects.

3. **Establishing a clearly-defined PPP frameworks for geothermal activities**
   Building on the recommendations from points (1) and (2), Indonesia can establish a comprehensive PPP framework specifically for geothermal activities. Although Indonesia already has a robust PPP framework, as detailed in Section 3.3, the energy sector, including geothermal, has not been a primary focus. By formally incorporating geothermal projects into the institutional PPP framework, these projects can leverage the various supports and incentives currently available for PPP initiatives in Indonesia, such as the viability gap fund and project preparation fund. This inclusion will ensure that geothermal projects benefit from the same level of support and regulatory clarity as other infrastructure projects.

4. **Deregulation of electricity market**
   In all those countries discussed, electricity market deregulations and liberalizations play important roles in building geothermal growth and renewable energy in general. Electricity market deregulations and liberalizations support geothermal growth by fostering a competitive environment that attracts private investment, which is essential for the capital-intensive nature of geothermal projects. By allowing geothermal operators to sell electricity through Power Purchase Agreements (PPAs) and on wholesale markets, deregulated markets provide long-term financial stability and access to diverse revenue streams, thereby encouraging more geothermal projects. Additionally, these reforms introduce market-based pricing mechanisms, enhancing the viability of geothermal energy compared to other energy sources and driving innovation and cost reductions in the sector. While implementing such deregulation in Indonesia may be challenging due to the current market structure, gradually introducing some level of deregulation over time will ultimately benefit the country's energy sector and its citizens.

6. CONCLUSION

Strategically integrating the best practices of public-private partnerships, customized to Indonesia's unique contexts, can significantly advance its geothermal sector. By drawing on global experiences and developing frameworks tailored to Indonesia's specific conditions, the country can optimize its geothermal potential, thereby enhancing national energy security and achieving sustainable development goals. This comparative analysis provides valuable insights for Indonesia and other emerging economies aiming to develop their geothermal resources through effective public-private partnerships. Implementing these strategies can lead to a more resilient and sustainable energy future for Indonesia and similar nations.

ABSTRACT

Geothermal exploration projects face significant challenges with high capital and high-risk conditions. The challenges also entail substantial environmental and social risks, necessitating rigorous safeguard measures to ensure sustainable development. During the exploration stage, the developer faces a limited financing option since the commercial financers hesitate to tackle exploration risk. The Government of Indonesia, the World Bank, and PT Sarana Multi Infrastruktur (Persero) ("SMI") launched an exploration financing and de-risking scheme called the Geothermal Resource Risk Mitigation (GREM) program.

This paper provides an in-depth analysis of safeguard requirements from the perspective of lenders, who play a critical role in financing these projects. Initially, the introduction delineates the importance of safeguard measures, setting forth the research objectives and offering a synopsis of international standards and guidelines that shape lender policies.

From the lender's perspective, the author examines the reasons for prioritizing safeguard requirements, their role in ensuring compliance, and the challenges and benefits of incorporating these requirements into financing decisions. Real-world insights are provided through case studies, including one from a geothermal field that applied for funding from a financial institution.

Evaluating the effectiveness of safeguard requirements is essential for continual improvement. The paper discusses monitoring and evaluation mechanisms and stresses the importance of assessing the impact of safeguard requirements on project outcomes. It also identifies areas for improvement in safeguard implementation.

In conclusion, this paper provides valuable insights into safeguard requirements in geothermal exploration projects from lenders' perspectives, enriched by lessons from a specific geothermal field's application to financial institutions. By understanding the key aspects and challenges of safeguard implementation, project stakeholders, including lenders, developers, and policymakers, can better navigate and enhance the sustainability of geothermal exploration projects.

1. INTRODUCTION

The geothermal development in Indonesia started from the colonized era with commercial utilization remarked through Kamojang Geothermal Power Plant (30MW) in 1983 (Darma, Imani, Shidqi, Riyanto, & Daud, 2021; Mansoer & Idral, 2015). Nowadays, Indonesia is top two geothermal countries in the world with a 2.417 MW installed capacity from approximately 23 GW total potential. It means that Indonesia only utilized around 10% of its total potential with an average additional capacity of around 60 MW per annum (ThinkGeo, 2024). There are 46 geothermal power plants developed by State-Owned Enterprises (SOE) and Independent Power Producer (IPP) in 17 geothermal working areas (Pambudi, 2023).

The government of Indonesia has a plan to utilize geothermal as a baseload to replace coal power plants and set the target of utilization to reach 5.799 MW in 2030 (Fadhillah, Tjendarsa, Damayanti, Purba, and Adityatama, 2024). The government target emphasizes the significant increase in the average of additional installed capacity toward 488 MW per annum from 2024 to 2030. This bold target needs to be achieved by catalyzing geothermal investment through better project attractiveness, including from a project economic perspective. Figure 1 shows the historical and target for geothermal power utilization based on PLN (2021), EBTKE (2023), and ThinkGeo (2024).

1.1 Challenges of Geothermal Project

Several challenges in the geothermal project derive from the lag of current utilization and the challenging target in 2030. Geothermal as reliable and sustainable energy to become baseload energy is well known as a high-risk project with long phases to reach the commercial operation date (COD). However, this reliability has several

challenges that might be faced and need to be solved by the company and government. Setiawan (2014) proposed the limiting factor of geothermal development that can be divided into three categories as explained in Table 1 below:

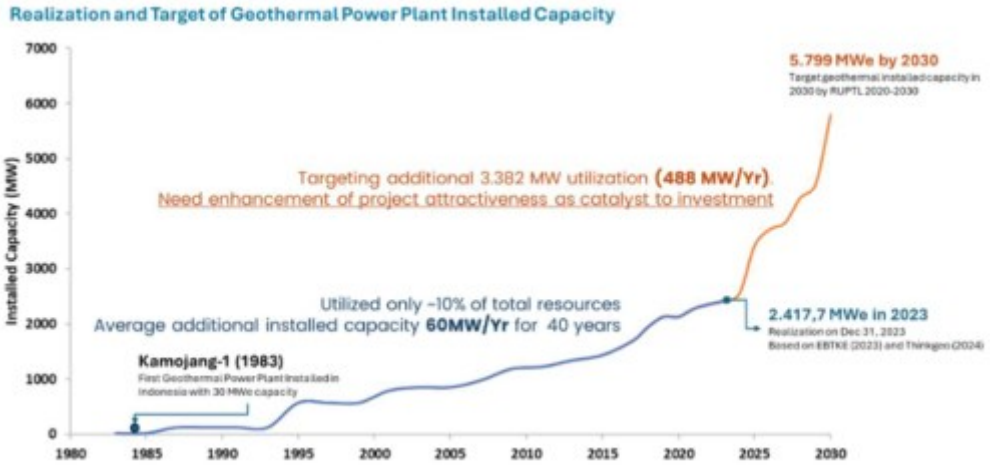

Figure 1: Indonesia geothermal power plant installed capacity and target for 2023 based on EBTKE (2023) and ThinkGeo (2024).

Table 1: Typical geothermal challenges in Indonesia.

Categories	Challenges	Remarks
Upstream challenges	High resource risk and complex uncertainty	Limiting factors in the upstream development stage cover the activity of geothermal exploration. The first limiting factor in the upstream stage is the lack of available reserve data for the auction process, resulting in unattractive investment. Many investors are concerned about the data and report quality, which does not briefly explain geothermal resource's extraction and development strategy and only focuses on the geoscience aspect without social and environmental considerations (Asian Development Bank, 2015 in Fan & Nam, 2018). It commonly needs long phases to develop geothermal energy, from 5–10 years until the commercial operation to mitigate the risk.
	High upfront/initial construction cost	The second limiting factor on the upstream side is high investment in the initial period, where the exploration phase is estimated to cost about 12 to 28 million USD, with an average of 7.6 million USD per exploration well (Purba et al., 2021b; Purwanto, 2019)
	Overlap with conservation/protected forests	The third problem is the location of geothermal working areas that overlap with production forests, conservation areas, and protected forests. Meijaard et al. (2019) found that there is a total of 13,025 MW of electricity potential from geothermal prospects in Indonesia, which are located within the protected forest (5,736 MW), production forest (2,416 MW), and conservation areas (4,873 MW)
	High relief terrain	Geothermal systems in Indonesia are mainly found along high-relief volcanic arcs and can be detected by surface manifestations that release water or steam at boiling temperatures at ground level (Hochstein & Sudarman, 2015). Due to the unique characteristics of volcanic locations where heat, rocks, and liquids interact dynamically, organically, and actively, Utami (2010) describes the various obstacles encountered when executing civil works in geothermal zones in Indonesia.
	Land acquisition issues	In general, the local community uses the flat area in Indonesia's volcanic area for agriculture or housing. Providing the acquisition cost for a family's livelihood in rural Indonesia is often tricky, especially if the land is their only asset. One mitigation strategy is allowing enough time for the landowner to move from one source of livelihood to another. Negotiation is frequently tough if the property buyer (geothermal developer or local government) demands a strict timeline for the landowner to leave the land they have worked on for years (Purba, 2021b).

Categories	Challenges	Remarks
	Poor existing	infrastructure condition The challenge of equipment inter-island mobilization in Indonesia is heavily influenced by infrastructure circumstances such as road access, transportation modes, and high-voltage electrical networks that would be utilized to drain electricity generated by PLTP. Furthermore, Indonesia's geothermal prospects are often located in high terrain forest areas that are distant from primary road access, both provincial and district highways. It makes mobilization of drilling equipment problematic. The existing infrastructure generally needs to be upgraded before equipment mobilization (Purba, 2021b).
Downstream challenges	Offtake market	The main factor limiting the downstream side of the geothermal development stage in Indonesia is the geothermal electricity market. According to Widiatmoro and Nusiaputra (2020), geothermal energy is considered environmentally friendly and has good security of supply and accessibility, but it is less affordable compared to other forms of energy. Moreover, in several area in Indonesia was already oversupplied and has limited grid system to absorb the generated electricity from geothermal energy.
	Single buyer	The first problem downstream is that there is only a single buyer for geothermal electricity in Indonesia: PT PLN (Persero). Lesmana et al. (2020) and Ministry of Energy and Mineral Resources Decree No. 37/2018 PT PLN (Persero) acted as the single buyer of electricity generated from geothermal power plants. Furthermore, the tariff of geothermal electricity is also regulated by the government by Ministry Decree No. 169.K/HK.02/MEM.M/2021, where the price depends on the location of geothermal prospects and is reviewed again by a price matrix based on exploration and development results (Widiatmoro & Nusiaputra, 2020). This regulation is resulting the weak bargaining process between the developer companies and PT PLN (Persero) in Indonesia's geothermal electricity business. Another problem on the downstream side is that geothermal power is not cost competitive with hydro or coal-fired energy generation, at least in the western Indonesia region (Purwanto, 2019).
Additional challenges	Local personnel competencies	Based on (Purba et al, 2021c; Umam et al, 2018), there is a lack of adequate competency in developing geothermal project since some current geothermal practitioners come from oil and gas industry that need several training and workshops before involved in geothermal project.
	Lack of public understanding on geothermal energy	The public's lack of understanding of the importance of geothermal projects frequently leads to rejection, resulting in delays in geothermal development initiatives. This circumstance is most common when geothermal projects are still in the discovery stage and local governments, development corporations, and local communities still recognize each other and have not yet created trust between each side—social dynamic condition and public acceptance issues that can be stopper of geothermal project.

1.2 Research Objective

The objective of this research is to offer insight related to safeguard requirements from lenders for the geothermal exploration project financed by the International Financing Institution and to provide general guidelines for investors of the geothermal developers to be eligible for funding and for supporting sustainable development. This research is based on a literature study that involved a review of reports on geothermal exploration projects, relevant provisions, publications, research articles, and guidelines on the Environmental, Health and Safety.

1. What is the significance of safeguard requirements in lending decisions?
2. What are the safeguard requirements for the geothermal exploration financing and de-risking facility?
3. What are the challenges to comply with safeguards requirements for the geothermal exploration projects under GREM facility?

2. ENVIRONMENTAL AND SOCIAL RISKS IN GEOTHERMAL EXPLORATION PROJECTS

The majority of geothermal potential is located in or close to forest areas has raised societal concerns about environmental and social impacts, especially in forests that play an important role in supplying fresh water, harbor

endangered wildlife, or have high cultural or religious values. The degree to which these social and environmental risks and impacts vary between geothermal power projects is not well understood. (PROFOR and the World Bank, 2019). Geothermal energy is a clean and sustainable source of power, however, major concerns or issues of environmental and particularly social are challenging. The developers are required to identify environmental, social, health and safety potential impacts or risks properly and comprehensively.

Geothermal exploration projects, while offering significant potential for renewable energy generation, are not without environmental and social risks. These risks can arise at various stages of the project, from exploration and development to operation and closure. Here's an elaboration on the environmental and social risks associated with geothermal exploration projects (Table 2).

Table 2: The environmental and social risks associated with geothermal exploration projects.

Environmental Risks	Social Risks
1. **Impacts due to Land Disturbance**: The construction of access roads, drilling pads, and infrastructure can result in habitat disruption and land degradation. This may impact local ecosystems, biodiversity, and soil stability. 2. **Water Resource Depletion**: Geothermal projects require large amounts of water for drilling, reservoir stimulation, and cooling. Over-extraction of water can lead to reduced groundwater levels, affecting local water sources, ecosystems, and agriculture. 3. **Water Pollution**: Chemicals used in drilling and well stimulation, as well as naturally occurring elements brought to the surface through geothermal fluids, can contaminate surface and groundwater. This pollution can harm aquatic life and pose risks to local communities relying on water sources. 4. **Induced Seismicity**: Injection and extraction of fluids into and from the geothermal reservoir can induce seismic activity. While most induced earthquakes are minor, there's a risk of larger events that could damage infrastructure and raise safety concerns. 5. **Air and Noise Pollution**: Drilling, machinery operation, and the release of gases like hydrogen sulfide can lead to air and noise pollution, affecting air quality and local communities' well-being.	1. **Land Acquisition and Resettlement**: Geothermal projects often require land acquisition, which can result in the displacement of local communities, affecting their livelihoods and traditional way of life. Inadequate compensation and resettlement processes can lead to social tensions. 2. **Cultural Heritage Impact**: Geothermal projects might encroach upon culturally significant sites or areas of historical importance to local communities. Disruption to cultural heritage can lead to social discontent. 3. **Community Health and Safety**: Potential exposure to geothermal gases and the industrial activities associated with exploration and power plant operation can pose health and safety risks to nearby communities. 4. **Employment Impact**: While geothermal projects can create job opportunities, there's a risk that local communities might not benefit as expected due to a lack of required skills or preference for outside expertise. 5. **Lack of Consultation and Participation**: Failing to involve local communities in decision-making and not seeking their input can lead to misunderstandings, opposition, and conflicts.

3. OVERVIEW OF GEOTHERMAL EXPLORATION FINANCING AND DE-RISKING FACILITY

Financing the geothermal exploration project is still considered a high-risk business for lenders as the resource uncertainty is still high. This section will further discuss the funding options for the geothermal exploration project that is currently available in Indonesia. Geothermal exploration is the riskiest phase of geothermal energy development and is challenging for developers. Thus, to scale up investment in geothermal energy by reducing the risks of early-stage exploration, the World Bank approved a loan in September 2019, accompanied by grants from the Green Climate Fund (GCF) and the Clean Technology Fund (CTF), two institutions supporting climate-friendly development.

There are two geothermal exploration de-risking facilities in Indonesia financed by the World Bank as follows:

1. **Geothermal Energy Upstream Development Project (GEUDP)**
   Geothermal Energy Upstream Development Project (GEUDP) is a government-sponsored exploration drilling collaboration program between the Government of Indonesia and the World Bank. The program aims to develop geothermal areas that have yet to be tendered, especially in eastern Indonesia, where the area's electrification ratio is low compared to the other parts of Indonesia (Apriani et al., 2018). The source of funds for the GEUDP program comes from the PISP Fund of USD 49 million, with matching grants from the Clean Technology Fund (CTF) of USD 49 million and the Global Environment Facility of USD 6.25 million. The

program also received grants from the New Zealand Ministry of Foreign Affairs and Trade (NZ MFAT) in the form of technical assistance that equals the amount of NZD 2.13 million.

MEMR, as the beneficiary of this program, will propose a geothermal prospect area to MoF to seek exploration support under the GEUDP program. Then, as the technical implementing agency, PT Geo Dipa Energi ("GDE") will conduct a preliminary assessment to see whether the proposed area is feasible to continue exploration drilling. Suppose the result shows that the proposed prospect area is viable, MoF will issue an assignment letter to GDE as the technical implementing agency and PT SMI as the financial manager to conduct the exploration drilling activities, which is supported under the GEUDP scheme.

The data acquired in the exploration drilling will be assessed by an independent party and discussed in the Joint Committee meeting to decide if the geothermal resource in the prospect area is proven and sufficient to be tendered by MEMR. Assuming that the resource is now de-risked, then MEMR will proceed with the tender process of WKP. In this stage, the participation of both public and private sector geothermal developers in the tender process is expected to increase as the geothermal resource risk has significantly reduced.

2. **Geothermal Resources Risk Mitigation (GREM) Project**
The GREM Project was initiated by the Government of Indonesia (GoI) through PT SMI in collaboration with the World Bank with the objective of accelerating the development of geothermal power generation projects in Indonesia. The ultimate objective is to further stimulate the development of a clean energy source in Indonesia by de-risking it through up-front avoidance of high-risk areas and effectively mitigating social and environmental impacts through good operational management. (The World Bank Group, 2019). Under the Indonesia Geothermal Resource Risk Mitigation (GREM) project, the financing will help public and private sector developers mitigate risks in the exploration of geothermal resources, including covering a part of the cost in case of unsuccessful exploration. The GREM project will also finance technical assistance and capacity building of key stakeholders in the geothermal sector.

   Under the GREM Project, a new Geothermal Resource Risk Mitigation Facility will be established. The new facility shall enable early-stage financing of geothermal projects for public and private developers to enable the increase of geothermal power generation capacities in the country. The Facility is envisaged to include three windows:

   a. Public developer window; and
   b. Private developer window.

   In regard to the GREM facility, it is designated to support the exploration drilling undertaken by geothermal developers who already hold the license or concession of geothermal working areas. The GREM facility is intended for SOE developers/subsidiaries of SOEs ("GREM Public Window") and private developers ("GREM Private Window"). One of the prerequisites for the geothermal developers to access this facility is that they already have the preliminary data of the prospect area/WKP. The unique feature of GREM is the availability of a de-risking facility or a risk-sharing scheme at which, in the event of an exploration failure, the developer does not fully bear the risks and costs of exploration.

The overview of geothermal exploration de-risking facilities available in Indonesia that just discussed is illustrated in Figure 2.

4.SAFEGUARD REQUIREMENTS FOR FINANCING DECISION

4.1 Lender Safeguard Requirements for Sustainability Development

Geothermal exploration projects carry inherent environmental and social risks that must be managed effectively. Safeguard requirements are crucial in mitigating these risks and ensuring sustainable project development. To ensure the success of a project, it is crucial to identify both the positive and negative impacts of its activities at the earlier stage of the project cycle. Therefore, a strategic approach and management plan can be developed to avoid, minimize, and mitigate or compensate for adverse risks and impacts of a project as well as enhance its positive impacts in compliance with the National laws, safeguard policies and standards.

The World Bank Group is deeply committed to fostering sustainable development globally, emphasizing the long-term preservation of the planet, social inclusivity, and reducing economic impacts on future generations. To align with this mission, World Bank-funded projects aim to enhance opportunities for inclusive participation, particularly among vulnerable groups such as women, children, individuals with disabilities, youth, and minorities, while promoting the responsible management of natural resources.

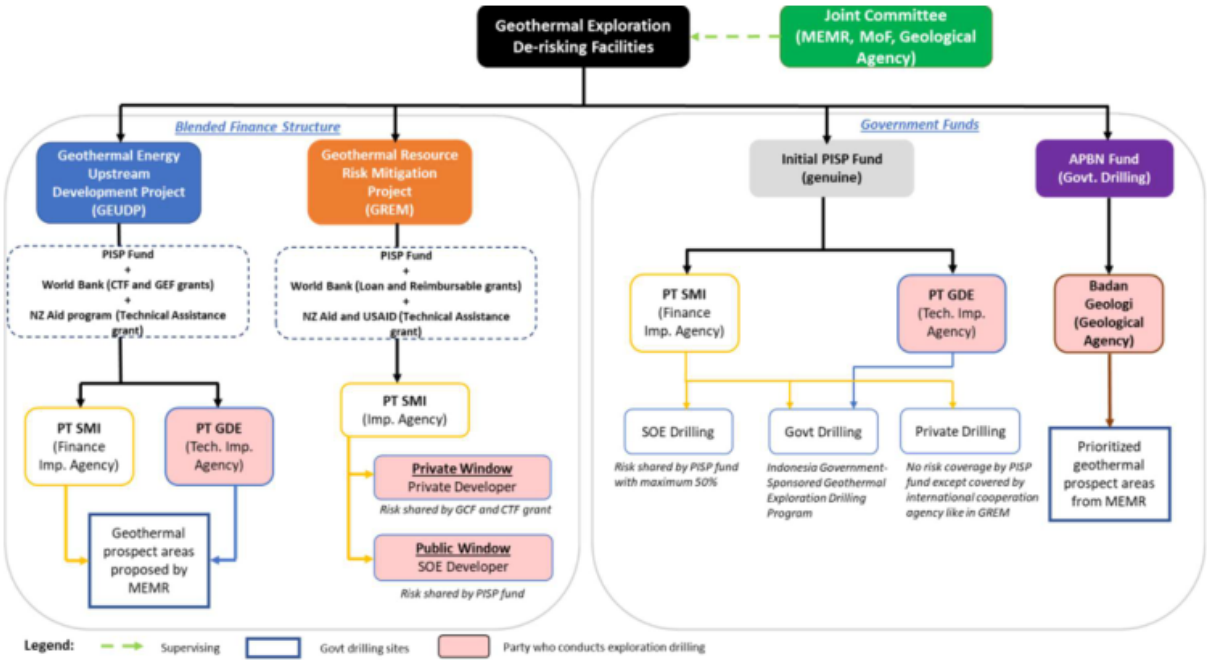

Figure 2: Overview of Geothermal Exploration De-Risking Facilities in Indonesia (PT SMI, 2022a).

The core tool for managing environmental and social concerns within these projects is the World Bank's Safeguard Policies. These policies establish a comprehensive system for assessing and managing risks and impacts, embedding environmental and social considerations into the decision-making process. They facilitate development through specific tools and participatory methods that ensure transparent and inclusive project design, which is crucial for engendering local community ownership.

These Safeguard Policies mandate the early identification and assessment of potential adverse environmental and specific social impacts during the project cycle. They also require that any unavoidable adverse effects be mitigated or minimized as much as possible, and they ensure that relevant information is disseminated in a timely manner to stakeholders, allowing for feedback on the impact assessments and mitigation proposals.

In August 2016, the World Bank introduced a more expansive set of guidelines known as the Environmental and Social Framework (ESF), which has been applicable to all new World Bank investment projects since October 1, 2018. The ESF broadens the scope of addressing environmental and social risks, offering a more comprehensive approach compared to the traditional Safeguard Policies.

Nevertheless, projects initiated before the ESF's implementation date, such as the Geothermal Resource Risk Mitigation (GREM) facility, continue to operate under the older World Bank Operational Policies (OPs) and Bank Procedures (BPs). To optimize these projects' approaches to environmental and social governance, it is recommended that they reference the Environmental and Social Standards (ESS) outlined in the ESF alongside the existing OPs/BPs. This integrated approach can enhance the projects' strategies for managing environmental and social issues, ensuring they adhere to the most current and effective sustainability practices.

As a financial intermediary, PT SMI has ten elements of the Environmental and Social Safeguard (ESS) Procedures that are commensurate with the World Bank policies, consist of 1)ESS-1: Assessment and management of environmental and social risks and impacts; 2) ESS-2: Labor and working conditions; 3) ESS-3: Pollution prevention and abatement; 4) ESS-4: Safety, health and security; 5)ESS-5: Land acquisition and resettlement; 6) ESS-6: Biodiversity conservation and natural resources management; 7) ESS-7: Indigenous peoples and local community; 8) ESS-8: Cultural heritage; 9) ESS-9: Energy conservation and environment-friendly energy; and ESS-10: Consultation and grievance mechanism.

4.2 The World Bank Safeguards Policies for the GREM Facility

World Bank safeguard policies are designed to prevent and mitigate undue harm to people and their environment in the development process. As the Bank's environmental and social agendas have evolved, its safeguard policies have also shifted from focusing on mitigating the potential environmental and social damage toward a more comprehensive focus on the sustainability of projects (a shift from do no harm towards do good). As such, the Bank's social and environmental safeguard policies seek to ensure that relevant measures, capacities and processes are in place, and that their application helps the Bank's borrowers decide what actions and programs need to be

taken to ensure the environmental and social soundness of projects. Safeguard policies also provide a platform for the participation of stakeholders in project design and selection and have been an important instrument for building ownership among local populations.

Table 3: The World Bank ESS, Safeguard Policies (OPs/BPs) and the New Key Elements of the Standards (Modified from The World Bank Environmental and Social Framework, Implementation Update, September 2020).

The ESF	OPs/BPs	New Key Elements
ESS1: Assessment and Management of Environmental and Social Risks and Impacts	OP/BP4.01(Environmental Assessment)	Integrates Environmental and Social Assessment; includes requirements related to non-discrimination and social inclusion; proportionality and adaptive management; use of the ESCP
ESS2: Labor and Working Conditions	OP/BP4.01 (Environmental Assessment) and EHS Guidelines	Prohibits child labor and forced labor, heightened focus on OHS, grievance mechanisms
ESS3: Resource Efficiency and Pollution Prevention and Management	OP4.09 (Pest Management) and EHS Guidelines	Promotes efficient management of energy, water, and other resources and materials; hazardous materials management; pesticides; GHG assessment mandate
ESS4: Community Health and Safety	OP/BP4.37 (Safety of Dams) and EHS Guidelines	Assess risks and impacts on communities; Design of safe and resilient infrastructure, equipment operation, products, services, road safety, hazardous materials; emergency preparedness
ESS5: Land Acquisition, Restrictions on Land Use and Involuntary Resettlement	OP/BP4.12 (Involuntary Resettlement)	Greater clarity on treatment of state land, land titling, access to common resources, voluntary transactions, forced evictions
ESS6: Biodiversity Conservation and Sustainable Management of Living Natural Resources	OP/BP4.04 (Natural Habitats) and OP/BP4.36 (Forests)	More detail and descriptive definition of habitat; expanded requirement to assess and mitigate impacts on biodiversity including in primary supply chains; biodiversity offsets; management of living resources in additional sectors (e.g. agriculture)
ESS7: Indigenous Peoples/Sub-Saharan African Historically Underserved Traditional Local Communities	OP/BP4.10 (Indigenous Peoples)	Clearer definitions of IP, requires FPIC in specified circumstances
ESS8: Cultural Heritage	OP/BP4.11 (Physical Cultural Resources)	Enhanced consultation with affected communities, intangible heritage
ESS9: Financial Intermediaries	OP/BP 4.01 (Environmental Assessment)	Establish E&S procedures commensurate with FI nature, risk level and impact
ESS10: Stakeholder Engagement and Information Disclosure	Consolidates WB Engagement Provisions	Meaningful consultation, access to information and grievance redress through the life of project

Each of the World Bank's policies plays a crucial role in ensuring that World Bank-financed projects not only meet strict environmental and social standards but also engage positively with affected communities, thereby supporting the overarching goals of sustainable development and social inclusiveness.

The World Bank environmental and social safeguard policies triggered by the geothermal exploration project are follow:

OP/BP 4.01 known as the Umbrella Safeguards Policy, delineates the environmental assessment process essential for compliance with other safeguard policies. This policy is crafted to enhance the environmental and social soundness and sustainability of investment projects by integrating environmental and social aspects into decision-

making processes. Essentially, the Environmental Assessment (EA) evaluates a project's potential environmental risks and impacts in its area of influence, examines project alternatives, and identifies ways to improve project selection, siting, planning, design, and implementation. It also encompasses mitigating and managing adverse environmental impacts throughout project implementation. A vital component of the EA is the screening process, initiated as early as possible, to determine the necessary scope of environmental assessment appropriate to the potential impacts and risks. Geothermal exploration projects typically fall into Category A or B, with Category A for projects with broader significant impacts and Category B for those with localized, manageable impacts.

OP/BP 4.04 focuses on the preservation of natural habitats, aiming to support environmentally sustainable development by promoting the conservation and rehabilitation of natural habitats and their functions. This policy protects habitats that are legally protected, officially proposed for protection, recognized by local communities, necessary for maintaining viability of protected areas, or recognized as having high conservation value. It mandates a stringent assessment of potential impacts on biodiversity and restricts significant conversion or degradation of critical natural habitats, ensuring any intervention is justifiable by substantial net benefits and includes appropriate mitigation measures.

OP/BP 4.36 addresses the strategic utilization of forests to reduce poverty sustainably while integrating forest management into economic development and preserving essential environmental services and values of forests. This policy restricts financing projects that may cause significant conversion or degradation of critical forest areas or habitats, ensuring forest conservation and sustainable management.

OP/BP 4.11 outlines the measures for protecting physical cultural resources (PCR) that might be affected by project activities. This is particularly relevant in regions like Indonesia, where geothermal manifestations may be considered sacred by local communities. The policy requires the development of PCR Management Plans and procedures for chance findings as part of the ESIA and ESMP processes.

OP/BP 4.10 emphasizes the importance of engaging with Indigenous peoples through free, prior, and informed consultations, especially where projects affect areas with Indigenous presence or collective attachment. It necessitates obtaining broad community support and implementing culturally appropriate benefits and mitigation strategies through an Indigenous Peoples Plan (IPP) or Framework (IPPF).

OP/BP 4.12 tackles involuntary resettlement, aiming to minimize direct economic and social impacts that cause displacement or loss of livelihood. Projects must be sited to avoid or minimize these impacts, and where unavoidable, comprehensive resettlement plans must be developed and consultations with affected communities conducted.

OP/BP 4.37 pertains to the safety of dams, requiring that any dam construction associated with a project meet stringent safety standards overseen by competent professionals. This includes specific safety measures for design, construction, operation, and maintenance, integrated into legal agreements and monitored for compliance.

4.3 Environmental and Social Management Framework (ESMF) of The GREM Facility

The World Bank designed environmental and social safeguard policies for supporting borrowers in the development and implementation of projects that are environmentally and socially sustainable. PT SMI as a Financial Intermediary in collaboration with the World Bank has prepared the GREM Environmental and Social Management Framework (GREM ESMF). The document details the environmental and social safeguard policies, principles, procedures, institutional arrangements, and workflows in avoidance, minimization, or mitigation of any adverse environmental or social impacts of infrastructure projects supported by the Geothermal Resource Risk Mitigation Project (GREM).

Table 4: The Key Safeguard Instruments and Permits Requirements for the GREM Facility.

Stage	Safeguard Instrument/Permit	Remarks
GREM Facility Application (Proposal)	Approved UKL – UPL	Has been approved by the authority. To comply with the applicable GoI laws and regulations
	ESIA and ESMP (Approved Final Draft)	To comply with the World Bank policies and GREM ESMF. ESMP is specifically prepared for managing the impacts and risks of the project.
	Environmental Permit/Approval	Has been issued by the Ministry of Environment and Forestry
	Forest Area Use Permit, if applicable	If the permit is not yet issued, the developer is required to provide details

Stage	Safeguard Instrument/Permit	Remarks
		on the current status of the permitting process
Financing Approval Process	Final ESIA and ESMP	To be approved by PT SMI and the World Bank. Finalization and disclosure of the UKL-UPL, ESIA, and ESMP documents are minimum requirements for financing approval by the Financing Committee.
Before Construction and Drilling Activities Commence	Sub-plans and procedures of the project ESMP	Sub-plans and procedures that need to be prepared are subject to the results of Environmental and Social Due Diligence (Corrective Action Plan).
	Final Stakeholder Engagement Plan (SEP) and Grievance Redress Mechanism (GRM)	These documents shall be prepared in project preparation from the outset of the ESIA study. Involve stakeholders at the early stage of the project cycle to ensure their participation and input.
	Land Acquisition and Resettlement Action Plan (LARAP) and Livelihood Restoration Plan (LRP)	If any land /assets and/or any loss of income (livelihood) are affected by the project. No work begins until land acquisition and resettlement has been completed.
	Indigenous People Plan (IPP)	If triggered in the ESIA and ESMP
	Physical Cultural Heritage Management Plan (PCHRMP) and Chance Find Procedure (CFP)	Despite the physical cultural heritage is not triggered, the Chance Find Procedure is still required.
	Gender Action Plan (GAP) and Gender Based Violence (GBV) Risk Management	This is an instrument as required by the World Bank policy for proposing gender equality in the design and implementation of projects, and to protect women in the project area from gender-based violence
	Forest area Use Permit (PPKH)	Issued by the MoEF or the authority in accordance with the applicable related regulation
	Surface Water Extraction Permit (SIPPA)	Issued by the Ministry of Public Works and Housing or the authority in accordance with the applicable related regulation
	Contractor – ESMP (C-ESMP) and Standard Operation Procedures	The C-ESMP is detailed Project ESMP that shall be prepared by an awarded Contractor and approved/cleared by PT SMI and the World Bank before site work begins

To qualify for financing under the Geothermal Resource Risk Mitigation (GREM) facility and ensure compliance with World Bank policies, developers must meticulously implement their projects in line with the provisions outlined in the GREM Environmental and Social Management Framework (ESMF). This includes adherence to all mitigation plans specified in each safeguard instrument and any supplemental instruments to the satisfaction of the overseeing bodies.

As a fundamental condition of eligibility for GREM facility financing, developers are required at an early stage to submit several critical documents. These include the Environmental Management Effort and Environmental Monitoring Effort (Upaya Pengelolaan Lingkungan - Upaya Pemantauan Lingkungan, or UKL-UPL) along with the Environmental Permit/Approval. Additionally, an approved final draft of the Environmental and Social Impact Assessment (ESIA) and the Environmental and Social Management Plan (ESMP) must be included as integral parts of their proposal documents.

The essential safeguard instruments and permits necessary for obtaining and maintaining eligibility under the GREM facility are comprehensively listed and described in Table 4. This table serves as a crucial reference for developers to ensure they meet all the required environmental and social compliance standards, thereby facilitating a smooth and compliant project development process under the GREM facility.

The key safeguard instruments and permits that are required for the GREM facility are summarized in Table 4.

5. THE CHALLENGES AN LESSONS-LEARNED OF SAFEGUARD COMPLIANCE FOR THE GREM FINANCING

5.1 The Challenges in the Safeguard Compliance in Geothermal Exploration Project

For projects under the Geothermal Resource Risk Mitigation (GREM) facility, adherence to both the applicable national laws and regulations of Indonesia (GoI regulations) and the World Bank Safeguard Policies is required. A crucial element of project compliance involves identifying and addressing any discrepancies between these two sets of guidelines. Discrepancies are documented in a comparison detailed in Table 5, which presents key features of both the GoI regulations and the World Bank's policies.

In instances where conflicts arise between the national laws/regulations and the World Bank Policies, the principle of applying the highest standard is adopted. This approach mandates that the project should adhere to the more stringent standards with regard to minimizing social and environmental impacts. Essentially, wherever there is a difference in requirements, the project must default to the regulations that offer the greatest level of protection for the environment and social welfare. This ensures that the project not only fulfills its legal obligations but also aligns with best practices in sustainable and socially responsible development.

Table 5: Comparison between GOI Laws/Regulation and the World Bank Policy.

No.	Topic	Indonesian Regulation	The World Bank Policy
1.	Applicable Safeguard Instrument	Geothermal exploration requires only an Environmental Management Plan and Monitoring Plan (UPL-UKL), regardless of potential impacts, according to GOI Regulation No. 5 of 2021 Appendix I in the Energy and Mineral Resources Sector.	OP4.01 requires an assessment of safeguard instruments depending on the classification of activity based on risk
2.	Associated Facilities	The GOI laws and regulations consider project activities discretely – consider each phase as a separate environmental permit process, and thus require separate application and obtainment of approvals accordingly (GOI Regulation No. 22 of 2021 Appendix III)	OP4.01 Environmental Assessment requires an assessment of associated facilities where they are considered part of the Project (either geographically, or over time),
3.	Utilization of Forest Area	Remove barriers to carrying out geothermal exploration and exploitation activities in forests and protected areas - take into account the low-impact use of ecosystem services and that geothermal is accepted and increasingly considered as a nationally strategic activity (Geothermal Law No. 21 of 2014, Article 5, Section 2)	The World Bank policies (OP 4.36 and 4.04) have maintained their requirements and standards regardless of the activities and require full impact assessment / significant mitigation before sub-project appraisal, or not funding certain exploration activities – that may result in degradation or removal of critical habitats
4.	Involuntary Resettlement	Land acquisition plan based on a feasibility study, the project suitability to the spatial plan.	Different planning instruments must be prepared to achieve the objectives of the policy and must cover all aspects of the proposed resettlement (LARAP)
5.	Eligibility of Indigenous People	Indigenous Peoples are covered by the land acquisition and resettlement legislation once they have been legally recognized	IPs are covered when screening identifies the presence of IPs as per characteristics in OP4.10 policy (which does not require any legal recognition).

In addition to the regulations gaps as a challenge, the case study for the safeguard issue is the geothermal exploration project in Wae Sano village, Sano Nggoang District, West Manggarai Regency, East Nusa Tenggara Province. The Wae Sano Geothermal Exploration Project under GEUDP was established in 2017 with funding

from the World Bank. The full broad community support from the community as the World Bank requirements were not achieved. The local people opposed the project, because the Wae Sano geothermal exploration is in people's living space and will have a significant environmental and social impact on them. Consultations with stakeholders from local government, community leaders and the community had been conducted, but the community's stance has not changed. Following consultation with the stakeholders in Wae Sano village on December 2022, the World Bank canceled financing for a geothermal exploration project.

According to Raffaele Cataldi (2001) and Afandi et.al (2023) Social acceptance is an important requisite for the smooth implementation of geothermal projects, especially at the exploration phase. It is known that in several geothermal exploration projects in Indonesia are still facing Societal Challenges due to the presence of negative stigma towards geothermal exploration projects.

Another challenge relates to land use. Most geothermal potential in Indonesia is in or close to forest areas. This has raised societal concerns about environmental and social impacts, especially in forests that play an important role in supplying fresh water, harbor endangered wildlife, or have high cultural or religious values. Environmental and social impacts and risks associated with geothermal power development are complex and significant and the degree to which these risks and impacts vary between geothermal power projects is not well understood.

5.2 Lessons Learned of Safeguard Compliance for the GREM Financing

From the lender's perspective, adherence to safeguard requirements, national regulations, and World Bank safeguard policies, including those outlined in the Environmental and Social Management Framework (ESMF), enhances a geothermal developer's eligibility for funding and demonstrates a commitment to sustainable practices. During the preparation of a geothermal exploration project, PT Sarana Multi Infrastruktur (PT SMI) identified several areas where developers encountered significant challenges with these safeguards requirements. The key findings are summarized below:

1. Safeguard Instruments Preparation (ESIA, ESMP, and others):
    - The scope of the Environmental and Social Impact Assessment (ESIA) required by international standards is broader than the national requirements (UKL-UPL or AMDAL). Developers need to prepare safeguard instruments that comply with the GREM ESMF to align with World Bank policies, the Resettlement Policy Framework (RPF), and Indigenous Peoples Planning Framework (IPPF).
    - The project area of influence was inadequately defined in the ESIA documents, failing to include project footprints, ancillary, and associated facilities.
    - The screening and scoping processes were improperly conducted, which failed to appropriately categorize the document and define the ESIA's scope. Engaging subject matter experts in this process is crucial.
    - Baseline data collection was inaccurate and did not reflect the actual conditions of sensitive receptors for both dry and wet seasons.
    - Information on project activities was limited, making it difficult to assess potential impacts and risks comprehensively. The initial project design was unavailable during the ESIA preparation, and design alternatives necessary for impact assessment and mitigation were not considered.
2. Project Organization and Team Capacity:
    - There was a notable lack of dedicated Environmental, Health, and Safety (EHS) personnel to manage the project, coupled with limited knowledge and experience in geothermal development, which are crucial for implementing and monitoring safeguards.
3. Stakeholders Engagement and Consultation:
    - There was insufficient engagement and consultation with stakeholders, as well as inadequate dissemination of information regarding the potential impacts and risks of the proposed geothermal activities.
4. Land-related Issues:
    - Developers faced challenges in the permitting process to secure areas within protected forests, unclear land ownership, and issues related to communal and social forestry lands. The effort required for land acquisition was compounded by community reluctance to sell or lease land, especially productive agricultural land.

Effectively preparing a project by incorporating safeguard instruments and engaging stakeholders comprehensively will bring numerous benefits. Meeting safeguard requirements not only increases local community acceptance but also ensures smoother implementation for geothermal exploration and contributes to sustainable development goals.

6. MONITORING AND EVALUATION OF THE SAFEGUARD COMPLIANCE

Evaluating the effectiveness of safeguard requirements is essential for continual improvement. The monitoring and evaluation of safeguard compliance are divided into two stages during the GREM duration, namely monitoring and evaluation of all safeguard-related requirements prior to the exploration financing agreement signing, and monitoring the implementation of the actions plan in the safeguard instruments during construction, exploration drilling, well testing activities.

The safeguard instruments of UKL-UPL, ESIA and ESMP including Gender Action Plan are mandatory documents for the proposal of the GREM facility. Before submitting the proposal, the Project Management Unit of PT SMI as a Financial Intermediary will advise the sub-borrower during the safeguard instruments preparation to comply them with the World Bank policies and standards.

After proposal submission, there will be an Environmental and Social Due Diligence (ESDD) process from the financing division of PT SMI supported by an Independent ESDD Consultant to indicate any red flags and find any gaps that need to be fulfilled by the sub-borrower before financing agreement signing.

At minimum, the list of requirements for the environmental, social, health, and safety due diligence process for the GREM facility to be taken into account by the sub-borrower is presented in Table 6.

Table 6: List of Requirements for the Environmental, Social, Health and Safety Due Diligence Process for GREM Facility.

Aspect	Remarks
HSE Policies and Organization	HSE organization capacity and competency to manage environmental and social risks. Show responsibilities and any relevant company policies.
Environmental Aspect Summary	Summary of the main environmental context, and key issues that may be faced. Summary of studies completed to date. The environmental aspect summary must covering the AMDAL or UKL-UPL document and environmental baseline, the developers also need to present potential impacts and planned mitigation that need to be included but not limited to: matrix of impacts on the environment, air quality and odor, noise, groundwater, surface water quality, surface hydrology and hydraulics, biohazard potential/terrestrial ecology flora and fauna, visual impact, sustainability and climate change, drilling waste management process, domestic waste management, potential geohazard and geotechnical issues, borrow to use permit/PPKH status, and other necessary permits.
Environmental and Social risks	Description of the environmental and social context and identification of any sensitive receptors, issues, risks.
Baseline data	Detail the data parameters for impact environmental and social assessment of geothermal exploration drilling activities in accordance with National Regulations, PT SMI's ESS Procedures and WB policies. Description/scope of baseline studies completed, underway or planned and who is undertaking the studies.
Project Area of Influence	Define the Project Area of Influence (AOI), and cumulative impacts. Describe the basis and show its map.
Safeguard instruments	List the safeguard instruments in accordance with GREM ESMF, SMI's ESS procedures, and the World Bank Policies. Provide status and plans for completion.
Enviro and social permits (e.g. UKL- UPL)	Status of the permits that relate directly to drilling, their scope (and match with drilling plans). Identify any issues or gaps. Summary of required environmental and social permits and approvals as per legislation that have been obtained or in the process of being obtained or will be obtained in the future.
Standard Operating Procedures (SOPs)	List and status of Environmental and Social SOPs required during construction, drilling and well testing
Social acceptance	The level of acceptance of the main project with the community. Summarize any community engagement made to date, key issues and possible barriers to the project. Describe plans for any mitigations and ongoing social engagement and CSR activities. The summary of social impact assessment that needs to be covered but not limited to socio-cultural, socio-economic, geothermal education, traffic, transport, and community safety, community displacement, community health and safety, stakeholders' response, and other related impact.
Social engagement	Status of community engagement, level of acceptance, plans for further engagement before, during and after drilling. The information can be presented not only using paragraphs but also using a table with include social engagement activity type, date, time, location, number of local people involved, name of the leader from the

Aspect	Remarks
	community, name of representative from the company, key takeaway from each engagement, etc.
Land status & ownership	Ownership of the land required for the drilling, facilities and access roads. Public / private, forestry or protected or heritage areas. Maps, aerial photography, commentary on status. Commentary on the plan for land acquisition as may be required for the project. Status of land ownership over the areas required for water supply, access road and well pad upgrade or construction. Plans for land acquisition or lease.
Compensation	Compensation that may be required for land acquisition or use, or for general nuisance to community. Scope of compensation, methods for distribution.
Direct heat use Projects	Identify any direct heat use projects that may be associated with the project (if applicable)

7. CONCLUSION AND DISCUSSIONS

The conclusion of the paper emphasizes the critical role of safeguard requirements in the financing and sustainable development of geothermal exploration projects. It highlights the intricate challenges and substantial risks associated with these projects, particularly in terms of environmental and social impacts, and the necessity for robust safeguard measures to manage these risks effectively. This approach is crucial for improving safeguard implementation practices and enhancing the overall sustainability and success of geothermal exploration projects.

For the effectiveness of safeguard implementation, it is imperative to consider but not limited to the followings:

1. A comprehensive ESIA and ESMP will help the developers to identify, avoid, minimize, and mitigate for adverse impacts and risks as well as enhancing the positive impacts of project to achieve project sustainable development. The capacity building on the World Bank safeguard requirements to the developers and their ESIA consultant is beneficial to enable them in assessing the impacts and the mitigation plans thoroughly and comprehensively to avoid, minimize, and mitigate or compensate for adverse impacts to comply with the World Bank policies and Good International Industry Practice (GIIP) standards. This also will make the ESIA a reliable basis for decision-making;
2. ESMP shall be reviewed regularly during its implementation for any improvement on the mitigation measures of impacts due to new or non-anticipated impacts. The developers shall ensure effective implementation of the ESMP, which the potential environmental and social impacts being managed and mitigated effectively for sustainable development;
3. Consultations should be held with key stakeholders to determine potential concerns and issues associated with the project as early as possible in the project cycle and through the life of the project. The proposed project activities and its potential impacts shall be socialized to stakeholders including local communities transparently;
4. Capacity building to communities and other stakeholders on the geothermal development project is important to enhance their knowledge on geothermal energy as a renewable energy in comparison with other renewable energy sources. The public's lack of understanding of the importance of geothermal projects frequently leads to rejection, resulting in delays in geothermal development initiatives. This circumstance is most common when geothermal projects are still in the discovery stage and local governments, development corporations, and local communities still recognize each other and have not yet created trust between each side—social dynamic conditions and public acceptance issues that can be stopper of geothermal project. (Fadhillah et all , 2022 and 2023);
5. Multi-stakeholder collaboration and partnerships play an important role in the success of a project. The early involvement of the community and other stakeholders will build their participation towards the project. With continuous, transparent and effective communication about the project and its potential impacts and an approach that takes into account local culture, any concerns from the community can be discussed and solutions sought as early as possible. With this approach, It is expected that there will be no rejection of the project.

Keywords: FPIC, stakeholder engagement, Indonesia, geothermal

ABSTRACT

There is a growing recognition, bolstered by research and experience, that good stakeholder engagement helps reduce social risk and negative impacts while providing superior developmental outcomes to local communities, and overall lowers project costs to the developers, the financiers, and the government. Good stakeholder engagement is particularly important to identify social groups vulnerable to shocks due to the project and identify their distinctive needs and concerns. Among other stakeholders, Indigenous Peoples (IP) are particularly vulnerable to the loss of, alienation from, or exploitation of their land and access to natural and cultural resources. In recognition of this vulnerability, an increasing number of International Financial Institutions (IFIs) require their clients to obtain the Free, Prior, and Informed Consent (FPIC) of the affected Indigenous Peoples when such circumstances occur under the projects they finance. Projects often struggle though with precisely how to engage with a broad range of stakeholders, including importantly Indigenous and local communities, for lack of clear technical guidance.

This paper summarizes a recommended Technical Guidelines which will provide step-by-step procedures and concrete actions as pathways toward carrying out meaningful stakeholder engagement and achieving their FPIC where required, under the "Participation and Partnership Framework (PPF)" as the overarching conceptual framework. The PPF also suggests that this approach be made available not only for Indigenous communities but for any project when significant community risks are present. The Technical Guidance discusses how to do this by laying out three basic approaches that the project can use depending on the scale of risks and impacts as well as the characteristics of the affected people: FPIC- Standard, FPIC-Lite, and FPIC-Like.

1. INTRODUCTION

Indonesia has enormous potential and challenges in terms of development and renewable energy. Emerging global standards and IFIs have committed to supporting renewable energy and collaborating to speed the development of energy transition initiatives. Significant developments will necessitate using new energy sources such as solar, water, wind, and geothermal. However, renewable energy production and transition affect, and are affected by, the surrounding population throughout the project's operational life, including particularly Indigenous Peoples who retain deep cultural ties and rely on the natural resources of their home territories.

Meaningful stakeholder engagement (SE) is becoming more widely acknowledged as an essential component of social risk management. This is because it assists projects in obtaining a "social license to operate" and reduces the potential risk of rejection from affected people or criticism from civil society. In Indonesia, where experience is minimal, particularly in the public sector, stakeholder participation is frequently considered merely a consultation meeting or two for a safeguard document. Weak engagement from stakeholders often results in resistance from local communities, which can be avoided or minimized through meaningful stakeholder interaction.

Meaningful stakeholder engagement and processes to achieve and maintain community support are particularly important if the project affects Indigenous Peoples (IP) and will go a long way toward achieving the enhanced consultation standard of Free, Prior and Informed Consent (FPIC) that is required under many international standards such as the World Bank's Environmental and Social Framework (ESF) and IFC's Performance Standards (PS). A good understanding of how enhanced meaningful stakeholder engagement can lead to FPIC and what additional activities and documentation are needed to meet FPIC requirements will help renewable energy projects overcome potential social risks while minimizing compliance risks. A heightened awareness of international good practice on stakeholder engagement and FPIC in the renewable energy sector will also have a spill-over effect in other sectors since many principles, processes, and procedures on meaningful stakeholder engagement and FPIC are similar across sectors.

These Technical Guidelines (TG) also follow up on the "Stakeholder Engagement & FPIC 101" workshop held in February 2023 by the World Bank Indonesia which had these key takeaways:

1. Practitioners need guidance on clear processes to reach consent and criteria to recognize it, and which is acceptable to all parties including international financiers. All stakeholders need to agree upfront on processes to reach and confirm consent, including who will give consent.
2. Convincing a project's senior management of the value of meaningful SE and FPIC with concrete case examples, especially to secure necessary budget, is key.
3. SE should start early and continue throughout project preparation and into implementation, but the challenge is that SE and FPIC are typically seen as a matter of compliance. As a result, SE including that with Indigenous Peoples, is often limited to a public consultation meeting to meet policy requirements just before project approval.
4. It is important to embed FPIC processes in legally binding assessment processes such as Environmental and Social Impact Assessment (ESIA) to enhance the legitimacy of FPIC and ensure it is conducted as a process. Agreements made between the project and the community (and the local government as relevant) when prepared as a condition of consent should be in legally binding documents.
5. Significant legacy issues including pre-existing discontents and intra-community tensions should be assessed upfront and addressed if they could negatively affect the project before the project initiates an FPIC process on project specific matters. Experience shows that unresolved legacy issues can negatively affect FPIC processes that may otherwise be adequate and make it difficult for the project to obtain a "social license to operate."

Lastly, all users of these TG need to consider them as one part of a broad range of social and environmental safeguard policy document guidance. The ten Environmental and Social Standards of the World Bank, like their cousin policy documents of the other IFI and affiliated entities, need to be seen in conjunction with those policies along with the myriad national, regional, and sectoral guidance that have emerged these recent years.

2. WHAT'S FPIC?

"Free, Prior and Informed Consent," like the term "Indigenous Peoples", has no universally agreed upon definition. For the World Bank, consent refers to the collective support of affected Indigenous Peoples' communities…for the project activities that affect them reached through a culturally appropriate process. It may exist even if some individuals or groups object to such project activities....(Environmental and Social Standard 7, ESS7, para. 26).

In both international and national use, FPIC has heretofore been applied exclusively to Indigenous Peoples. FPIC is an approach of involving Indigenous Peoples in the discussion and decision-making of projects that will affect them. It is grounded on the recognition by international legal instruments of the collective rights of Indigenous Peoples and it is considered a substantive framework and integral component of the Indigenous People's exercise of their right of self-determination and to their rights to land, territories, and resources. It allows Indigenous Peoples to give or withhold their consent to any project design, implementation arrangements, and/or matter impacting them or their customary lands, territories, and resources. Importantly, "consent" does not merely mean saying "yes." It also means saying "No" or delaying a "No" or "Yes" until the affected Indigenous Peoples are informed appropriately and accurately on all project-related matters which will impact their lives and lifeways. The FPIC process thus builds on and expands ESS10's emphasis on "meaningful consultation." FPIC refers to both (i) a process of seeking consent, and (ii) an outcome in terms of a decision and should include documented proof of both.

These Technical Guidelines recognize the positive benefits that FPIC bestows on both the affected communities and the projects that are projected to be implemented in, on, or near their lands and proffers such benefits to non-Indigenous communities as well as those communities recognized as Indigenous. The Participation and Partnership Framework thus is not limited in application solely to Indigenous-affecting projects but to all those projects either Indigenous or facing significant environmental or social risks. FPIC can be a boon to them all.

It is important furthermore to note that FPIC is an agreement that continues in full validity past the decision point of any positive consent approval following good faith negotiations (see below). FPIC agreements may be suspended or withdrawn if the agreements achieved are seen not to be followed. Also, we should recognize that FPIC concerns group collective rights not individual rights and so the consent process does not require unanimity of opinion nor grant any individual or community a veto over the collective domains and collective will of the people participating in the FPIC process or of the communities and peoples in question.

Under the IFI Indigenous Peoples' policies, FPIC is generally required under any one of three circumstances as described by the World Bank:

a) have adverse impacts on land and natural resources subject to traditional ownership or under customary use or occupation;

b) cause relocation of Indigenous Peoples…from land and natural resources subject to traditional ownership or under customary use or occupation; or

c) have significant impacts on Indigenous Peoples'…cultural heritage that is material to the identity and/or cultural, ceremonial, or spiritual aspects of the affected Indigenous Peoples'…lives.

(ESS7, para.24)

And what does each of the four "FPIC" components mean?

- **Free**—without coercion, intimidation, manipulation, threat, or bribery; an independent process of decision-making.
- **Prior**—the right to follow their own decision-making process—accurate and full information is received, consent has been sought sufficiently in advance, before any project activities have been authorized or commenced, and that the time requirements of the indigenous community's consultation/consensus processes have been respected.
- **Informed**—information is provided in a language and form that are easily understood by the community, covering the nature, scope, purpose, duration and locality of the project or activity as well as information about areas that will be affected; potential economic, social, cultural, and environmental impacts--both positive and negative—as well as all involved actors, and the procedures that the project or activity may entail. It is the right to have accurate, accessible, sufficient information on matters for decision-making in a culturally compatible manner.
- **Consent** — a collective and independent decision of affected Indigenous Peoples after following their own process of decision-making. It is the right of Indigenous Peoples to give or withhold their consent to any decision that will impact their lands, territories, resources, and lifeways (From: United Nations Permanent Forum on Indigenous Issues (UNPFII), Report of the International Workshop on Methodologies Regarding Free Prior and Informed Consent, Document E/C.19/2005/3, endorsed by the UNPFII at its Fourth Session).

The four different components, "Free," "Prior," "Informed," and "Consent," add substantial meaning to the FPIC approach. Each of these elements has its own meaning, principles and processes, and manner of implementation. They are, however, interrelated and should be applied in an integrated and holistic manner. The first three components (Free, Prior, and Informed) qualify and set the conditions of "consent" as a decision- making process. Therefore, "consent" is required before any action takes place (Prior), is independently decided (Free), and is based on accurate and sufficient information, and full understanding (Informed) for it to be a valid outcome of a collective decision. Experience has also taught that these attributes of FPIC—and their allied principles of transparency, inclusion, and mutual respect—best also carry over into the post-FPIC decision period of FPIC agreement implementation. An Indigenous Peoples Plan (IPP) composed of mitigation measures, compensation and benefit-sharing measures reached in agreement with local Indigenous Peoples should--like the FPIC process itself--be guided by the principle of upholding the collective rights of Indigenous Peoples.

From this perspective, although a positive "consent decision" takes place at a certain time and cannot be simply revoked, FPIC operational principles of transparency and collaboration can serve as a gateway to ongoing engagement for the life of the project and any FPIC agreements approved by that consent decision must be carried out in good faith.

3. THE PARTICIPATION AND PARTNERSHIP FRAMEWORK (PPF)

The FPIC-compliant "Participation and Partnership Framework" (PPF) recasts project-affected communities as partners in project design and implementation, rather than as a group of external stakeholders to consult or negotiate with. As is described in more detail below, the PPF seeks to apply the FPIC principles and the Good Faith Negotiations (GFN) approaches throughout the project life and treat project affected communities as partners in project design, implementation, monitoring and discussions on course corrections, to help the project gain and maintain a social license to operate. The PPF aims to do so by building and maintaining positive relationships among stakeholders including the Affected Communities, contractors, governments, civil society organizations and the project proponents, based on transparency, inclusion, and mutual respect, while applying a risk-based approach to avoid overwhelming any stakeholder unnecessarily. Project experience upon which the PPF was based includes that garnered by Indigenous Peoples Organizations and international development specialists such as the Nepal Federation of Indigenous Nationalities (NEFIN) and the Regional Council of Authorized [Indigenous] Representatives ([RCAR] of Sakhalin, RF) and secondly by the firm Cross-Cultural Consulting Services (CCCS) working in Indonesia, Tanzania, Ethiopia, Russia, and Nepal

Consistent with the principles of the GFN provided in the Guidance Notes of the World Bank's ESS7 and IFC's PS7, the PPF serves as the overarching framework for these TG by:

a) Providing detailed guidance on how to apply the principles of FPIC and GFN during the project implementation (FPIC Implementation) phase, in addition to the project preparation (FPIC Negotiation) phase.
b) Treating Indigenous and local communities as partners in project design and implementation rather than external entities to negotiate with.
c) Fashioning a three-sided alliance of partners composed of Indigenous/local communities, local governments and the project as critical partners in key discussions and long-term planning.
d) Allowing both Indigenous and local communities to participate in decision-making processes to develop and implement risk mitigation and benefit generation measures, including monitoring, evaluation, and grievance redress, as part of the IPP or Social Impact Management Plan (SIMP) governance.

The Project Office (PO), through FPIC Coordinator who coordinates with relevant units within the PO, will implement and fund project activities including risk mitigation, benefit generation and FPIC processes. They will report to the relevant government agencies and their own financiers on project performance including compliance on E&S matters and stakeholder engagement. Importantly, a senior management, ideally the project director or deputy director, should represent the project and participate in discussions and decision making at the Working Group (WG)/Governing Board (GB) on matters that concern affected Indigenous and non-Indigenous communities (hereafter, called "FPIC Communities").

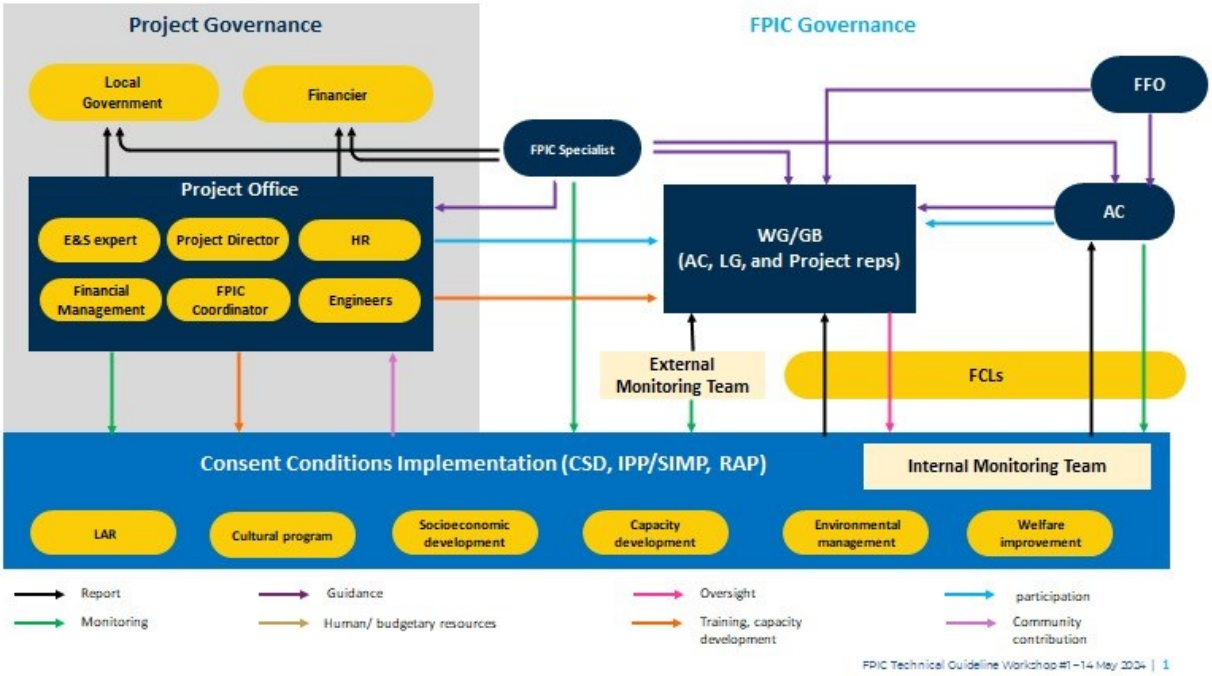

Figure 1: Project - FPIC Governance, both on the project side (left) and the community side (right).

The Advisory Council (AC) consists of representatives from the FPIC Communities and leads their discussion on FPIC processes and project matters that concern them. The AC will participate in the WG which is a tripartite decision body (communities, local governments, the project) that negotiates FPIC, and the GB is its successor that oversees FPIC implementation if FPIC is obtained. FPIC Community Liaisons (FCL) "connect" the AC and members of the FPIC Communities, facilitate discussions in-between consultation meetings and flag issues to the AC, so that the AC can make decisions based on broad-based and inclusive deliberative processes. The Working Group (WG)/ Governing Board (GB) serves as the "decision body" on project matters that concern affected communities while the AC served as the "consent body", independent of the WG/GB.

In between both sides there is the FPIC Specialist who will bridge the project and the community and facilitate their negotiations and who might also serve as the independent External Monitor (EM) during FPIC implementation to monitor adequate implementation of consent conditions including risk mitigation and benefit

generation measures. As will be mentioned below, the FPIC Specialist will play the role of the FFO where risks are not significant and having an independent FFO does not justify the cost; this would most likely occur only when the FPIC-Lite approach is followed.

At the bottom there are Program Committees (PC) responsible for overseeing the implementation of consent conditions including risk mitigation and benefit enhancement measures. The PCs consist of community representatives, and report to WG and/ or GB. An internal monitoring team will monitor progress and performance of activities agreed upon as consent conditions including risk mitigation, benefit generation and capacity development. and report to the WG/GB, AC, and the project.

Detailed roles and responsibilities of respective players will differ between the FPIC Negotiation and Implementation Phases.

4. ADJUSTING FPIC TO PROJECT RISK LEVEL

As a form of stakeholder engagement, FPIC can take different forms and styles. Not all projects must pursue the full FPIC process--its scale and extent can differ depending on project circumstances. FPIC strategies should be responsive to the needs of the Affected Communities as well as the requirements of the financier and the regulator, so that rounds of consultations and other aspects of an FPIC effort can be calibrated to match likely project impacts and avoid overwhelming any stakeholder unnecessarily.

Depending on project circumstances, the scope of FPIC could be expanded or reduced. For example, when Indigenous and neighboring non-Indigenous communities are both affected by the same project, or when some Indigenous communities are subject to one of the three FPIC-requiring circumstances, but others are not, all members of the project-affected communities could be incorporated into the same FPIC process. A possible expansion of FPIC scope, including the pros and cons of such an approach, should be carefully evaluated in the context of FPIC planning.

Conversely, the scope of FPIC may also be limited to certain project aspects, such as when a linear project passes through multiple administrative units and requires FPIC only for a specific component. As stated in the World Bank's GN7 (para. 25.2): "In some projects, FPIC may be required only in relation to specific portions of land or aspects of a project. Examples include: (a) linear projects that pass through multiple human habitats, which may require FPIC for the component that traverses [indigenous peoples'] lands; (b) projects comprising multiple subprojects, some of which are located on [indigenous peoples'] lands, which may require FPIC for the subprojects located on those lands; and (c) projects involving an expansion of ongoing activities, which may require FPIC for the new project activities."

Experience has taught that there are at least three broad approaches to FPIC application:

a) FPIC-Standard: the aim is to achieve FPIC for a project which will significantly affect an IP community in full compliance with applicable IP standards requiring FPIC. These Technical Guidelines will set out this full and robust approach in the chapters following Part One while also touching on how the other approaches below can be utilized.

b) FPIC-Lite: for those FPIC-triggering projects likely resulting in more modest effects on the IP communities, less intensive consultations, studies, and documentation, while keeping the core principles of FPIC, can be sufficient to meet the applicable IP standards. An FPIC-inspired Indigenous Peoples Plan (IPP) may or may not be prepared depending on the requirement of the financier, or an FPIC-inspired SIMP may substitute the IPP together with a Stakeholder Engagement Plan (SEP) to document consultation processes that led to FPIC.

c) FPIC-Like: those projects that do not affect an IP community, but which involve significant stakeholder risks can apply parts of the FPIC Standard approach to build collaborative relationships with key stakeholders toward resolving their concerns in mutually acceptable ways that benefit all, thereby giving the project a "social license to operate. A formal consent statement—while desirable--may or may not be prepared because for this type of project, FPIC is typically not required by financiers or regulators. An FPIC-inspired SIMP would be the operational equivalent of an FPIC-inspired IPP.

From this perspective, FPIC can become a guideway to good stakeholder engagement for most projects. Oxfam (2024:5) has recognized—and endorsed--this emerging global trend of applying FPIC to projects affecting a broad swath of communities Indigenous and non-Indigenous alike:

"The safeguard provided by the principles of FPIC is increasingly interpreted as a best practice standard for affected local communities who do not fit the international legal definitions of rights-holding Indigenous peoples. Many land-connected or frontline communities share similar socioeconomic and political characteristics and long-standing customary connections to land.…In this way, the principles of FPIC represent a best practice for a just

transition and sustainable development, and a crucial project safeguard that can increase the legitimacy of a project in the eyes of all rights holders and reduce the risk of social conflict. For this reason, it is one of the most important legal rights and safeguards for protecting human rights and fighting inequality."

The PPF recognizes this continuing value of the FPIC process and extends the principles and practices from the FPIC Negotiation Phase past a positive consent decision into the equally important FPIC Implementation Phase.

5. FPIC STAKEHOLDER ENGAGEMENT FOR GEOTHERMAL PROJECTS

Geothermal energy, while part of the renewable energy category, is somewhat distinct from other industries and so FPIC stakeholder engagement must take the industry's peculiarities into account when approaching project and community interactions. Its unique aspects that cause distinctive stakeholder risks and affects the outcomes of stakeholder management should be well considered, and detailed guidance be provided on stakeholder engagement and FPIC processes for geothermal development stages:

1. Preliminary and 3G Surveys (geological, geophysical, geochemical): Focus 2A
2. Infrastructure Preparation and Exploration Drilling: Focus 2A
3. Construction (of well pads, access roads, piping system, power plant, etc.): Focus 3A
4. Operation: Focus 4A

Throughout the long period of project preparation and implementation, the project needs to be careful to ensure that FPIC is implemented consistently with all ESS, and particularly with the ESIA process. This will enable affected communities to engage in the FPIC process with a good understanding of potential risks and benefits.

5.1 Long Time Frame

Geothermal project development commonly needs between five and ten years to fully move to commercial operation—and sometimes even longer. While this may be technically necessary, it raises some complications regarding local community engagement:

a) **Personnel turnover**: Contractors, developers, government and project staff, and community leaders in the latter stages of project development are usually not the ones that had initial discussions and reached initial agreements. Lack of awareness and lack of commitment to others' promises can cause a breakdown in communication and trust. The original individuals involved in negotiations or discussions may have been committed to any agreements made or understood, but these can be easily forgotten or ignored as the individuals who represent their parties change. Without documented records of initial understandings memories get hazy and misunderstandings are born.

b) **Legacy issues**: Personnel turnover is exacerbated at a larger scale when different developers and contractors carry out geothermal operations at various phases and stages of development, depending on the investment program that has been approved. In the case of private investment schemes, for instance, in which the developer changes between the preparation/exploration and construction stages based on the tender results, this presents the question of continuity of completion from the preparation/exploration stage to the construction stage and beyond into operation. Legacy problems at each step need to be reviewed and steps taken to resolve them.

c) **Unmet promises and unrealistic expectations**: During early contacts and consultations unauthorized or implicit promises may be made to deliver benefits (such as connecting the affected communities to the electrical grid or to provide energy free of charge) or that the project will be implemented soon. When these things don't materialize promptly due to unavoidable circumstances such as delays in bidding processes, time needed for the developer to secure funding, etc., the initial positive or at least neutral attitude to the project begins to turn negative.

d) **Community "Consultation Fatigue"**: Repeated meetings with the community over years leads to community cynicism and boredom especially during early phases when community consultations discuss the project in vague terms and the project cannot take on many of the concrete inputs from community members. The risk is particularly large when the same old issues get discussed each time new staff get on board or new developers get hired to start engaging with affected communities newly.

e) **Regulatory Changes**: Regulatory frameworks can change over time, affecting project permits, compliance, and financial incentives. These also may affect communities.

5.2 Negative Public Perception of Geothermal Projects

There is a negative perception of drilling activities for exploration due to frequently circulated stories which claim serious negative effects. Community fears are multiple and mainly environmentally focused:

a) Geothermal projects will lower the groundwater supplies and pollute the water with poisonous chemicals.
b) Geothermal projects will cause poisonous gases like H2S (hydrogen sulfide) to be released into adjoining communities.
c) Geothermal projects will all generate dust and noise due to the construction machinery itself and truck movement.
d) Geothermal projects will generate unpleasant odors, noise, or visual disturbances that can lead to mental health issues in people living near the project.
e) Geothermal projects will trigger landslides and earthquakes, and possibly floods as well.
f) Geothermal projects expose local employees to a range of safety hazards.

Economic and cultural risks also loom large:

a) Agricultural productivity will be harmed.
b) Tourist industry will be damaged as natural resources are harmed or tourists scared away.
c) Historical and sacred places will be damaged.
d) Local communities will not likely benefit from the project, especially in the early stages of the project as land is taken out of production to build project infrastructure.

As Adityatama, et al 2018; Umam, et al, 2018; Purba, et al (2020) indicate, such community concerns should be taken as genuine to avoid unnecessary community pushback. Geothermal projects should seek to bring affected communities along by honestly and transparently informing them as to the true nature, risks, and benefits in ways that are easy to understand for them, instead of explaining project risks and benefits in overly technical terms.

5.3 Informational and Compensatory Efforts are Critical

A significant informational and compensatory effort needs to be undertaken early on in project planning and initiation. The project needs to address community fears while not shying away from realistic and accurate risk assessments (along with planned mitigation measures). Yet highly complex technical issues are not easily conveyed in local community meetings, even if facilitated by skilled community workers; how to present them to the affected communities in an accessible format needs to be seriously considered (see Chapter Four, Focus 2A and Box 1 below). Extensive consultations with information sharing needs to take place from the start.

Communities should be entitled to:

a) Receive fair and objective information on risks and benefits of geothermal operations, including project risk management systems and emergency response mechanisms.
b) Benefit from geothermal operations through the corporate social responsibility (CSR) and/or community development programs.
c) Receive fair compensation for damages due directly to geothermal operations.
d) Participate in ESIA process and Environmental and Social Management Plan (ESMP) design and implementation.
e) Use fair and accessible Grievance Redress Mechanisms including judicial systems.

Information sharing and consultation process should go beyond community members directly or indirectly affected by the project. Developers in some countries—including Indonesia—are typically not too concerned with Non-Government Organizations (NGOs) and may not engage them from the start. Outreach to NGOs and Civil Society Organization (CSOs) is a critical part of the entire stakeholder engagement process. Neglecting such stakeholders can cost the project dearly during a later stage.

5.4 FPIC in Stages?

Geothermal projects are broadly classified into two phases: exploration and exploitation phases. The direct footprint of the first exploration drilling phase is typically limited to a few hectares of land for drilling locations, storing materials and drilling employee camps. This differs from the construction stage, which impacts larger areas, directly and indirectly. The FPIC process should be conducted differently at different phases given the different scale and scope of impact.

During the exploration phase, project impacts on local communities are typically limited other than loss of a limited size of land. Compensation should be paid for land loss at the fair replacement value per SPI 204. Those

community members outside the drilling site will not lose land or non-land assets and will thus not receive compensation. While this is legally compliant, it often frustrates many community members whose land will not be acquired as they feel they need to bear various, non-land risks from inadequate wastes and wastewater treatment to potential Hydrogen Sulfide (H2S) leakages including during the exploration phase.

Also, community members will unlikely make neat distinctions between the exploration and exploitation phases of a geothermal project. Pointing out that the main risks and benefits will only occur if the project progresses past the exploration stage may do little to assuage concerns of the local community who may well consider that the exploration phase is just the early phase of an exploitation phase that will come inevitably. They may just become "concerned" from the moment they hear the word "geothermal" which they may associate with some incidents that occurred in another island. Addressing impacts that will occur during the exploration phase only may well not satisfy them.

It may therefore make sense that FPIC-Lite approach is applied during the exploration phase, even though the size of impact and the characteristics of affected people may not require FPIC. It would involve extensive information-sharing and consultations with the community at large in addition to those whose assets would be directly affected. It would set out an agreement as to how the project and the community would engage during the initial exploration stage including exploratory drilling and prior to a decision as to whether to develop the project was made. While the focus will be on activities during the exploration phase, the potential scale and scope of impact that may occur during the exploitation phase, and possible time lag between the two phases, should also be discussed so that community members can make an informed decision based on a good understanding of the full spectrum of the project.

If it is decided that the project would move to the exploitation phase, a new and second FPIC process should begin. Firstly, where there is a significant time gap between the two phases, or different agents are hired to do the exploitation than the one who did the exploration, FPIC achieved at the exploration phase need to be renewed. This time the affected communities would be asked prior to construction beginning to give their FPIC for the project and the measures which would affect them. Similarly, any documents such as an IPP prepared during the first FPIC process would need to be updated as would any comparable SEP. This second FPIC process would best follow guidelines for a full FPIC-Standard process, the scale and scope of which would be adjusted depending on the nature and scale of impacts.

6. INITIAL ENGAGEMENT DURING SURVEYS AND EXPLORATION STAGE IN GEOTHERMAL PROJECTS

Initial stages of stakeholder engagement and FPIC preparation for geothermal projects are affected greatly by the particular nature of these projects as discussed above. As was noted therein, it's probably best to use the "FPIC-lite" approach when working with local and/or Indigenous communities affected by a geothermal project during the survey and exploration phase. Yet even so, there remains a need for extensive consultations since there is much misunderstanding of this type of project and it's best to have a neutral entity such as an FFO to serve as a mediator in discussions between developers and the host community. Also, as mentioned above, local community members, Indigenous or not, may not differentiate between the exploration and exploitation phases, requiring the FPIC process to consider more than the limited impacts that may occur during the exploration phase and refer to the potentially more significant risks that may occur during the exploitation phase.

This need for an added effort stands in contrast to the absence of statutorily required consultations since an Environment Impact Assessment (EIA) and its mandatory consultation process would not typically be invoked for the relatively small exploratory geothermal area. The consultation requirements for the lower UKL/UPL standard may not be sufficient to address community concerns.

During this stage, therefore, projects need to establish community outreach programs to inform about the project as it might be challenging to explain to the community in a clear and easy-to-understand way about the technology to be employed and how it would affect the community. The focus of such extensive consultations should be on education on geothermal risks and mitigation measures and possible benefits from the project. Such outreach efforts can include an overview of geothermal development in general, geothermal development in Indonesia, technical and environmental aspects of geothermal development, and potential impacts/risks of geothermal development and its mitigation measures.

The FPIC-lite approach must also tease out what promises might have been made or implied by the project and the community and clear and honest clarifications made at this point (dealing with "legacy" issues).

Yet even at this early stage, fears may emerge, and accidents occur. Stories will undoubtedly circulate of poisonous gas leaks, but policy lacks specific regulations discussing safe boundaries between drilling locations and residential areas. Furthermore, national health and safety guidelines are often not properly enforced, adding to the

doubts and confusion. For this reason, any initial FPIC-lite agreement should include specification of such distances and a system to monitor such—preferably with community co-participation. Furthermore, the developer can offset community perceived risks with a CSR benefits program even before a decision is made to fully develop the geothermal field. However, projects must be leery of overpromising jobs in this early stage since the need for technical skills will mean that few local jobs will be actually available at that time.

7. ACHIEVING SOCIAL LICENSE & FPIC IN GEOTHERMAL PROJECTS

Once the decision is made to move to the exploitation phase, a new phase of FPIC Process must begin. Whereas the initial survey and exploration phases might have sufficed with an FPIC-Lite approach, the full FPIC approach is probably necessary in this exploitation phase because the impacts are bigger:

- Drilling production wells and injection equipment
- A piping system
- A power plant
- An access road

At this point, community attitudes often begin to turn negative as a large external workforce is brought in and local cultural norms come under stress. They often become concerned about environmental risks (noise pollution, water pollution, induced earthquakes/landslides), foreign workers' influences, and diminishing skilled and non-skilled job opportunities.

Mass land clearance and associated loss of forests to build the access road, well pads, and basecamps often trigger community concerns related to loss of ecosystem services including clean water and agro-forestry opportunities, fears of wild animals' entering villages, and so on. Heavy equipment mobilization and massive soil movements often induce soil and water contamination, dirty roads, dust, or even injuries and fatalities. An extensive use of local water sources can induce contamination and loss of water resources. Health and safety risks related to H2S gas and blowout events can be a source of significant concerns (Adityatama, Purba, & Kristianto, 2018). Presence of large external work often forces raises local concerns about the different cultures and social values between local and non-local workers in daily interaction.

The FPIC process must consider all these fears honestly and transparently through an inclusive ESIA process. A well-crafted and facilitated FPIC process can keep affected communities informed of potential project environmental and social risk and impacts while also inform the project and the ESIA process of their needs and concerns in return. Potential benefit generation measures can also be discussed and agreed upon, including through the establishment of community development fund to which the project can contribute parts of the operating revenues to fund initiatives identified by community members themselves. As a result, affected communities will be able to gain a deeper understanding of project effects and mitigation measures and receive long-term benefits that may more than compensate potential residual risks, helping the project gain a social license to operate and become better able to manage risks that may unexpectedly occur despite all the management measures.

5. CONCLUSION: FPIC-COMPLIANT STAKEHOLDER ENGAGEMENT AS A PROJECT BONUS

While some projects have dreaded carrying out an FPIC process, experience shows that projects benefit by embracing the FPIC principles to build positive and long-lasting relations with affected communities and local governments in a spirit of participation and partnership. What might have been previously resisted as a project-complicating turn of events can develop into a multi-stranded bonus for the project that:

- **Deals with the Past**: through multiple rounds of stakeholder engagement, the FPIC process provides an opportunity to "press a reset button" by addressing any outstanding project "legacy issues" during the negotiations leading to an agreement.
- **Deals with the Present**: allows the project to come to an understanding with the local communities as to the impacts of the project, risk mitigation, benefits-sharing, and resolution of outstanding concerns/grievances culminating in an FPIC agreement.
- **Deals with the Future**: By building in an ongoing project-communities governance structure into the IPP/SIMP and similar instruments, the project can carry over the good will and trust that the FPIC process might engender into long-lasting collaboration with local communities.

Although, per international safeguards standards, "consent" can be granted or determined at only one point in time, any significant change to the project design, implementation arrangements, and/or expected outcomes may require the project to obtain FPIC for such changes. Project designs, and implementation schedules and arrangements, often change during implementation. Also, many unexpected incidents occur during implementation. It is therefore a prudent risk management strategy to establish a constructive partnership with

affected communities based FPIC principles without regard to compliance requirements. Doing so requires unpacking compliance requirements with regard to FPIC in light of strategic risk management and apply FPIC principles flexibly based on the needs of all key stakeholders including the project, affected communities and local governments. The results are sustainable outcomes that benefit all: stable financial return with good market reputation for (private) project proponents; the achievement of policy goals and the expansion of economic base for (local) governments; and the enhanced welfare level and voice for affected communities.

ABSTRACT

Geothermal energy projects, encompassing both electricity generation and direct use of geothermal heat, offer significant opportunities for national and local socioeconomic development. One tangible economic gain is the creation of new direct employment opportunities in construction and operation. Additionally, geothermal projects generate indirect jobs in upstream industries that supply and service the geothermal sector, such as equipment manufacturing. A vast number of induced jobs also emerge from the spending by those directly and indirectly employed in the geothermal industry, as well as from new economic activities enabled by improved access to electricity or heat, such as jobs in geothermal spas or geothermal-supported agricultural processes. The availability of reliable, stable, and affordable energy (both heat and electricity) can have a far-reaching economic impact by attracting industrial players to establish local operations and fostering the growth of small and medium enterprises. While economic benefits are more readily quantifiable, social benefits are equally important. These include enhanced educational opportunities, skill development and diversification, and the introduction of new services and infrastructure by geothermal developers. This paper summarizes key findings and recommendations from a recent report by the World Bank Energy Sector Management Assistance Program (ESMAP), titled "Geothermal Energy: Unveiling the Socioeconomic Benefits." The socioeconomic benefits are analyzed across four categories: participation of domestic companies in the geothermal value chain; geothermal employment and skill development; local development and benefit sharing; and gender equality and social inclusion.

1. INTRODUCTION

Geothermal energy offers a sustainable and reliable solution for many regions, providing a constant power source that can complement variable renewable energy sources and drive the energy transition forward. Unlike intermittent renewable sources like solar and wind, geothermal energy is available 24/7, making it a vital component in achieving energy security and grid stability. Geothermal energy is harnessed in two primary ways:

- Electricity Generation: Geothermal resources are utilized to generate electricity through technologies such as flash steam plants and binary cycle power plants. Flash steam plants use high-pressure hot water from the ground to produce steam that drives a turbine, while binary cycle plants transfer the heat from geothermal water to a secondary fluid with a lower boiling point, which then vaporizes to drive the turbine.
- Direct Use: Geothermal heat is directly applied in various sectors, including thermal baths, greenhouses, aquaculture, industrial processes, and district heating systems. This direct use of geothermal energy can significantly reduce energy costs and carbon emissions in these applications.

Additionally, there is potential to develop integrated systems that combine geothermal electricity generation with direct use applications. These cascading systems utilize geothermal effluent—fluid that has already been used for electricity generation—for lower-temperature applications, such as heating buildings or greenhouses. The versatility of geothermal energy in providing both direct heating solutions and electricity generation, and its ability to provide baseload power, makes it a crucial element in the transition to a sustainable and low-carbon future.

IRENA's World Energy Transitions Outlook provides a strategic roadmap to limit the global temperature increase to 1.5° Celsius. To achieve this target, the roadmap estimates that the installed capacity of geothermal energy must nearly double from 2020 levels by 2030 (IRENA 2023). This ambitious goal highlights the significant role geothermal energy can play in global climate mitigation efforts. Beyond its environmental benefits, expanding geothermal capacity presents a substantial opportunity to generate socioeconomic benefits for local communities and nations. These benefits include the creation of new business opportunities, job growth, skill development, and improved access to essential infrastructure, which can foster economic growth and enhance social inclusion. By

investing in geothermal energy, it is possible for governments to address climate change while simultaneously driving sustainable development and improving quality of life for communities.

This report delves into the socioeconomic benefits that can be actively shaped and significantly enhanced during project development and operation, across both electricity generation and direct use projects. Though important socioeconomic outcomes, this report does not explore broader sectoral advantages, such as the societal and economic benefits attributed to improved energy security, low-cost supply, and reduced greenhouse gas emissions.

In the context of this report, the explored socioeconomic benefits are grouped into the following four categories, as derived from the World Bank Sustainable Renewables Risk Mitigation guidelines (World Bank 2022):

1. *Participation of domestic companies in the geothermal value chain*: Developing and operating geothermal projects creates opportunities for domestic companies to offer goods and services, positively impacting economies. Contracts, varying in size, contribute to fiscal revenues, gross domestic product, and job growth.
2. *Geothermal employment and skill development*: Projects generate direct, indirect, and induced jobs and promote on-the-job learning and formal education opportunities. This results in new skills and greater diversity in the national workforce, promoting domestic employment.
3. *Local development/benefit sharing*: Developers collaborate with local communities to ensure lasting benefits and gain community acceptance. Approaches range from infrastructure improvements and skill development programs to revenue-sharing mechanisms.
4. *Gender equality and social inclusion*: Carefully designed geothermal projects can advance gender equality and social inclusion, addressing disparities based on social identity factors.

This article covers the first three categories in sequence, while gender equality and social inclusion are addressed throughout the paper, recognizing their intersectional nature and impact on achieving equity. The four categories are illustrated in Figure 1.

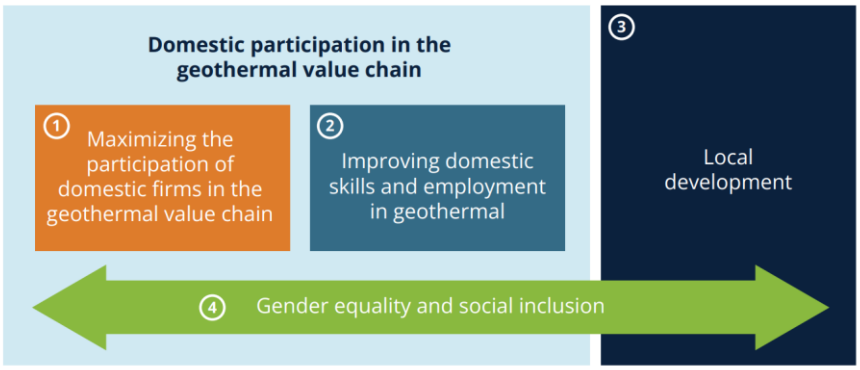

Figure 1: Socioeconomic categories.
(Figure source: ESMAP 2023)

2. LEVERAGING THE GEOTHERMAL VALUE CHAIN TO GENERATE SOCIOECONOMIC BENEFITS

Mapping the geothermal value chain is a crucial first step toward maximizing the potential socioeconomic benefits of geothermal projects. Localization opportunities can be created by identifying where goods, services, and labor can be sourced domestically, thereby adding value and bolstering a country's gross domestic product. Recognizing gaps in domestically available goods, services, and labor presents an opportunity to develop support programs to enhance the domestic industry's capabilities over the medium to long term. Figure 2 illustrates the geothermal value chain at a high level.

It should be noted that in Figure 2, manufacturing sits outside the value chain, as many components are produced outside the project countries. Geothermal turbines, condensers, cooling towers, and generators are highly specialized pieces of equipment, manufactured in only a handful of countries. However, some components, such as heat exchangers, pumps, valves, piping, and cladding, may be manufactured domestically.

Specific value chain activities that require highly specialized expertise and are less likely to be localized. In contrast, many countries present significant potential to localize activities within the value chain's construction and operation and maintenance (O&M) segments. Even when international companies are engaged, it is feasible and advantageous to employ local labor or subcontract portions of the work to domestic firms (ESMAP 2023).

It is important to acknowledge that each country will have a distinct level of domestic capacity in the geothermal value chain. This capacity is highly influenced by factors such as market maturity, availability of skilled labor, policies and regulations, and experience in related industries.

Note: Figure assumes a 25-year project life cycle.

Figure 2: Localization potential for services along the geothermal value chain. (Figure source: ESMAP 2023)

Governments can leverage project procurement to promote localization within the geothermal value chain. They can help domestic companies grow and develop by incentivizing domestic procurement of certain components and services by developers. However, such procurement practices should be carefully balanced to ensure they do not adversely affect project viability and tariffs.

For example, Türkiye and Indonesia have implemented policies to encourage domestic procurement in their renewable energy sectors. In Türkiye, the renewable energy law supports geothermal generation through a feed-in tariff program. This law included a support scheme called the Renewable Energy Resources Support Mechanism, offering a tariff top-up to power producers who use domestic mechanical and/or electromechanical components (ESMAP 2023). This incentivizes the procurement of domestic components.

In Indonesia, a less flexible approach has been adopted to nurture local manufacturing capacity. Geothermal developers are required to procure a set percentage of components and services domestically, with the exact percentage depending on the project's size. While this measure has successfully incubated local capacity, developers have noted that it limits flexibility and motivation to exceed the established requirements (ESMAP 2023).

Some governments have tailored procurement policies to favor women and disadvantaged groups. The Government of Kenya, for example, has tailored procurement requirements to favor women and disadvantaged groups. Initially, in 2005, Kenya mandated that all government entities procure at least 25 percent of goods and services from small and medium-sized enterprises (SMEs) to address unemployment. However, recognizing that some groups were still being left behind, the government introduced new legislation in 2013 requiring that 30

percent of all goods and services be procured from SMEs owned by youth, women, and disabled individuals. This regulation applies to geothermal entities like the Geothermal Development Company and the majority state-owned power utility KenGen (ESMAP 2023).

Clusters and industry associations also play a pivotal role in enhancing the capacities of the domestic industry. These entities contribute significantly to industry growth through activities such as training, facilitating stakeholder collaboration, and fostering an environment conducive to technology transfer and research and development. For example, Iceland's Renewable Energy Cluster is a nonprofit organization that unites 34 members from across the country. This includes educational and research organizations, energy companies, engineering and consultancy firms, and start-ups, all working together to create a platform that supports entrepreneurship and the export of geothermal knowledge and technology. In Indonesia, the Indonesian Geothermal Association (INAGA) plays a crucial role in supporting industry development by actively participating in the creation and review of geothermal regulations and offering continuous input to the government on related issues. Additionally, INAGA fosters industry collaboration and knowledge sharing through seminars, panel discussions, and conventions.

Crafting specialized financial products can help domestic companies access the capital they need to participate in the geothermal value chain and achieve scale. For example, they may require financing to adapt their business operations, acquire equipment, or hire and train new staff. Such tailored financial solutions help to overcome financing barriers and facilitate greater participation in the industry (ESMAP 2023).

Türkiye has scaled up the participation of domestic companies in the geothermal value chain through strategic financial incentives, particularly in geothermal greenhouses. The Turkish government worked with financial institutions like Ziraat Bank and the Agricultural Credit Cooperative to offer low-interest loans with flexible terms, including a principal grace period of up to two years. Investors can also access grants from the Ministry of Agriculture and Forestry and a national rural development program to further bolster their business case (IRENA 2022).

These financial supports have greatly increased participation in the geothermal sector, particularly through geothermal-heated greenhouses, leading to substantial downstream socioeconomic benefits. For instance, a 71.7-hectare project in Aydin produces 20,000 tons of tomatoes annually and employs 750 people, while another greenhouse in Kütahya produces 35,000 tons of tomatoes and employs 1,100 people. These targeted financial incentives have fostered economic growth and job creation in local communities (ESMAP 2023).

3. EMPLOYMENT CREATION AND SKILLS DEVELOPMENT

In 2021, the geothermal sector provided direct employment to approximately 196,000 individuals globally, more than doubling from 2020 (IRENA and ILO 2022). China leads with 78,000 jobs, followed by the European Union with 60,000, and the United States with 8,000.

Construction and O&M generate the most direct employment across a geothermal project's life cycle. While construction roles are more abundant, they tend to be short-term. Conversely, O&M positions, although fewer, offer employment over the entire lifespan of a geothermal plant. For example, a 50 MW project would create about 155 person-years of construction jobs and 35-60 permanent O&M jobs over 30-50 years, the equivalent of up to 3,000 person-years (ESMAP 2023). Note that the definition of a person-year can vary based on different contexts. A person-year is calculated by dividing the total number of hours worked by all employees on a project by the typical number of hours worked in a year. The creation of induced jobs, although challenging to quantify, can be substantial for geothermal projects. These jobs may arise from greater energy access, availability of heat to scale agricultural or industrial applications, or increased growth of domestic industries due to greater energy reliability.

As of 2022, women held only 22 percent of the jobs in the geothermal sector (ESMAP 2019). The gender disparity is even more pronounced in on-site geothermal jobs and skills roles, including those in construction and operations & maintenance (O&M), where an ESMAP survey found that female participation ranged from zero to 20 percent at most (ESMAP 2023). These roles have traditionally been male-dominated due to the requirement of technical STEM (science, technology, engineering, and mathematics) education, where women have historically been underrepresented.

Over the past four decades, the percentage of women in the geothermal workforce has indeed risen. In 1980, it was only 10 percent. However, this figure also suggests that without intervention, the geothermal sector will not achieve gender equality until 2100 (ESMAP 2023).

Organizations such as Women in Geothermal (WING), along with forward-thinking governments and companies, are working to change these trends. Proactive programs and policies to bring more women into STEM education,

recruit and retain female talent, narrow the gender pay gap, and showcase female leaders are making concrete differences. For example, LaGEO, a government-owned entity responsible for geothermal development in El Salvador, has taken significant steps to improve female employment. LaGEO operates two geothermal plants: one in Ahuachapán with an installed capacity of 95 MW, and another in Berlin with a capacity of 109.4 MW. Currently, 25 percent of LaGEO's staff are women, encompassing both administrative and technical roles (ESMAP 2023).

To further enhance this ratio, LaGEO has implemented policies such as flexible working hours and remote working options, and created female-friendly facilities, including a dedicated nursing room for new mothers. A notable achievement has been increasing female participation in traditionally male-dominated technical roles. By prioritizing women for short-term maintenance roles during major overhauls of the geothermal generation units, LaGEO has boosted female participation in these roles by 30 percent, from 22 women in 2016 to 83 in 2022 (ESMAP 2023).

Geothermal direct use projects hold immense potential for local job creation across various sectors such as agriculture, tourism, and industry. These projects can be stand-alone or complement power generation projects by utilizing excess heat. The types of jobs created depend on the specific end use of geothermal heat. In Poland, a study comparing 10 municipalities with geothermal projects to a control group showed significant employment growth, particularly in the trade and service sectors. Geothermal spas and recreational centers were key drivers of this growth, especially in smaller municipalities, highlighting the potential of geothermal projects to catalyze rural tourism and economic development (Kurek et al. 2021). Industrial uses like district heating improved residents' quality of life but had a lesser impact on employment structures.

Geothermal applications in agriculture, such as geothermal-heated greenhouses and food drying, offer significant yet underexploited potential for job creation. These applications can boost production, reduce food wastage, and create a variety of skilled and unskilled jobs, especially in developing countries where agriculture is the largest employer. Geothermal projects can contribute to gender equity and support women, who play a central role in food production. Opportunities for women in geothermal direct use projects are considered greater than in power production due to the diverse job types available. For instance, in Iceland's Blue Lagoon spa, 58% of jobs are held by women, while in Mexico's Deshidratador Geotermico de Alimentos de Nayarit food drying project and Türkiye's Caldiran Geothermal greenhouse project, women hold 80% and 75% of jobs, respectively (ESMAP 2023).

Despite over a century of using geothermal resources for electricity production, many countries still lack the necessary human resources to support the industry's growth, limiting the potential for domestic employment.

Recruiting highly skilled individuals is the greatest challenge. An ESMAP survey found that 72% of developers reported difficulties in hiring high-skilled labor domestically, with 29% facing this challenge often and 43% occasionally. The hardest roles to fill include geoscientists, geothermal modelers, production and reservoir engineers, drilling specialists, and plant engineers. Medium-skilled roles present occasional recruitment challenges for 43% of developers, while low-skilled roles are the easiest to fill, with 93% of respondents finding local community members who can be trained on the job (ESMAP 2023).

Governments and developers are addressing skill shortages by introducing new geothermal curricula and sending individuals abroad for training in established geothermal markets. For example, Iceland and El Salvador have implemented programs to address the education gap in geothermal expertise for international and regional audiences. Iceland's Geothermal Training Program (GTP), launched in 1979 under the Centre for Capacity Development, Sustainability, and Societal Change (GRÓ), provides intensive hands-on training and tailored programs to strengthen geothermal expertise in developing countries. Since many countries lack geothermal-specific education, the GRÓ GTP has trained 766 fellows from 65 countries, with some advancing to master's or doctorate degrees (ESMAP 2023).

In El Salvador, a partnership between GRÓ GTP, LaGeo, and the University of El Salvador established a five-month geothermal diploma program. In 2022, the program attracted 29 students from various Latin American countries, focusing on gender equality with 44 percent female participants (ESMAP 2023). This initiative provides geothermal training in the native language of participants, making El Salvador a growing hub for geothermal education in Latin America. These programs demonstrate how international collaboration can meet educational needs in countries without sufficient demand for their own geothermal training programs.

Additionally, developers often hire individuals lacking geothermal-specific experience and provide on-the-job training. For example, Indonesia-based Supreme Energy and PT Geo Dipa Energy offer training programs for community members to become plant operators, technicians, field chemists, and well testing officers. PT Geo Dipa Energy also provided welding training to 40 villagers, offering both theory and practical classes, along with certification (ESMAP 2023).

Supreme Energy, founded in 2007, is an Indonesia-based independent power producer. The company has two operational plants, with a total of 170 megawatts of installed capacity, and another site in development. It employs 187 staff; of these, 117 work at the two operational geothermal plants. The team at Supreme Energy has had a strong focus on acquiring and retaining quality talent, and the company has grown quickly over the past 15 years. Although Indonesia's geothermal industry benefits greatly from the wealth of expertise in the country's well-developed domestic oil and gas industry, there are still skills unique to the geothermal industry that require time and effort to develop.

Early in their operations, companies working in geothermal energy struggled to retain experts in the geosciences field, such as geologists, geoscientists, and geophysicists. Given the limited number of qualified subsurface specialists, and the high demand for their skills, employees were often recruited by other companies. High turnover rates presented a business challenge. Rather than recruit talent from abroad, as many companies do when talent is not easily available domestically, Supreme Energy's human resources team devised a strategy to grow talent in house. They decided to hire a cohort of 10 new graduates with geoscience backgrounds and put into action a plan to provide on-the-job learning and an array of professional development opportunities. Most of the new recruits were given the opportunity to study abroad, either in New Zealand or Iceland, to further develop their specialized knowledge. The strategy proved successful, and the company now has a competent geoscience team.

The company has also recognized the opportunity to recruit experienced staff from the oil and gas sector—including electrical and mechanical engineers, environmental engineers, biodiversity specialists, health and safety experts—who can then receive specialized geothermal knowledge once they step into their new roles. The company's induction training program complements classroom learning and on-the-job training with job shadowing, whereby a new hire conducts day-to-day work with an experienced peer in a similar role.

At the power plant level, it has also been a top priority for Supreme Energy to hire members of the local community. Since the specific skills required are not always easily available within the communities surrounding project sites, the company launched a geothermal development program for outstanding associate's and bachelor's degree holders from surrounding communities. Those selected enter a yearlong program, which includes four months of in-class learning, conducted in cooperation with a local university. They then transition to eight months of on-the-job training, after which the trainees are assigned to various roles, including power plant operator, mechanical and electrical technician, field chemist, and well testing officer.

To expand the geothermal workforce, it is important to disseminate information about job opportunities. Initiatives such as student competitions, mentorship programs, internships, and apprenticeships are instrumental in introducing individuals to career paths in the sector. For example, the US Department of Energy's Geothermal Technologies Office runs an annual student competition called the Geothermal Collegiate Competition. This competition engages students from across the country in solving real-world problems related to geothermal energy. It serves a dual purpose: inspiring a new generation of geothermal scientists and stakeholders, and contributing to research and innovation for the expansion of geothermal energy.

In 2022, the competition focused on planning a direct use project, requiring teams to conduct site identification, resource and demand assessments, conceptual design, and stakeholder engagement. The winning team from the University of Oklahoma was awarded $10,000 for designing a system to repurpose six abandoned oil and gas wells to provide geothermal energy for educational and municipal buildings, including those operated by the

Absentee Shawnee Tribe and Citizen Potawatomi Nation (ESMAP 2023). As a result of this in-depth exposure to the geothermal industry, several team members, originally enrolled in the oil and gas program, chose to pursue advanced studies focusing on geothermal energy. This competition highlights how student competitions can open students' eyes to potential career prospects and pathways in the geothermal sector.

Some governments have successfully integrated incentives into the project procurement process to encourage developers and subcontractors to train and hire domestic or local labor. Jobs created at the local level within communities surrounding geothermal project sites can have extensive socioeconomic benefits and greatly enhance social acceptance of these projects (as detailed in the following section). Roles that can be readily filled by local community members include construction laborers, drivers, security personnel, cooks, cleaners, community engagement liaisons, and administrative staff. With appropriate training, individuals can also be hired for field and pipeline maintenance, as well as plant technician and operator positions.

For example, governments can incentivize domestic hiring in geothermal projects through several strategies. One effective approach is to request developers to produce a plan detailing how they will employ domestic and local workers. This plan ensures that developers design a strategy for recruiting domestic staff and encourages subcontractors to hire locally. It outlines the types of roles that could be filled by the local population and may include plans for training the local workforce to upskill individuals to employable levels.

Another strategy involves providing incentives for developers to meet specified targets for local or domestic employment. For instance, developers could earn additional points during the proposal evaluation stage for committing to these targets, which may become contractual obligations, such as in power purchase agreements. These incentives can be further refined to encourage the hiring of women and socially disadvantaged groups.

Additionally, developers may be required or incentivized to implement and fund education, apprenticeships, and training programs for the domestic workforce. This could involve contributing to the establishment of higher education programs, supporting existing or developing new vocational training programs in welding, electrical work, plumbing, and masonry, and offering apprenticeships or on-the-job training. By providing practical, hands-on training specific to the geothermal industry, developers can ensure that trainees receive employment post-training. These training and education programs can also be tailored to target women and socially disadvantaged groups, further promoting inclusive workforce development.

4. LOCAL DEVELOPMENT AND BENFIT SHARING

Nurturing a positive and enduring relationship with local communities is crucial for developers to gain trust and secure a social license to operate in the geothermal sector. Establishing such a relationship typically involves contributing to lasting benefits within these communities and exceeding the requirements of legal social and environmental frameworks to compensate for losses incurred during project development. Developers have many motivations to share benefits beyond gaining acceptance for project development. Sometimes, benefit sharing is driven by a need to attain favorable environmental, social, and governance ratings or to secure financing, while in other cases, it is driven by the desire to create a positive company image.

To effectively share benefits with local communities, developers must prioritize timely and transparent communication, conduct detailed consultations, and implement collaborative programmatic interventions. It is imperative for developers to strike the right balance between their realistic capabilities and communities' aspirations.

Three primary categories for benefit sharing can be explored:

Improvements or additions to local infrastructure and services: This could include building or improving local infrastructure, or assessing how geothermal resources can be shared for general community purposes, such as heating or agricultural applications. This type of benefit is commonly provided by developers. For example, nearly all developers contribute to community infrastructure, such as building roads, which are often necessary for site access. A survey conducted for this study revealed that out of 15 developers, 13 (87 percent) invested in local infrastructure (ESMAP 2023). Examples of such contributions include constructing schools, plants for processing local agricultural products, wells and water distribution systems, sports areas, roads and bridges, traditional markets, renovations to places of worship, and health clinics. Exploring the potential for community members to utilize geothermal heat through the development of a direct use project is less common, but it would offer numerous benefits to the community, including new jobs and additional sources of income.

Enhancing skills and capability at the community level: Education and training programs are essential to ensure that local community members can easily access new job opportunities created by geothermal projects. These training programs may focus on geothermal-related skills or other sectors, such as improving agricultural practices for local farmers, or building computer or literacy skills. According to a survey of developers, 73 percent offer

training to prepare for geothermal employment, 53 percent provide training to improve performance in other areas like literacy and computer use, and 80 percent focus on enterprise development (EMSAP 2023). For example, in Nicaragua, Polaris Renewable Energy supports educational opportunities for children, youth, and adults, including women. The company provides computer training for teachers and supplies tablets and computers to schools. Additionally, Polaris enhances farmers' technical capacity, including assistance with product commercialization (ESMAP 2023).

Revenue-/ownership-sharing arrangements: Revenue and ownership-sharing arrangements in geothermal projects can involve offering equity stakes, establishing beneficial taxation systems, or directing a portion of revenue to community-controlled entities. Of the 15 developers surveyed, only 33 percent had set up some form of revenue-sharing arrangement (ESMAP 2023). Several examples are provided below:

- In New Zealand, the Māori owned entity Tauhara North No. 2 Trust holds equity stakes in multiple geothermal developments, directing revenue from these operations, estimated at NZ$6 million per year, to grants and programs supporting Māori people (ESMAP 2023).
- In Kenya, the Energy Act 2019 mandates that geothermal licensees pay royalties on the extracted resources' value, with royalties apportioned to the national government (75 percent), county government (20 percent), and local community (5 percent). The community's share is managed through a trust fund established by local community regulations (ESMAP 2023).
- In El Salvador, LaGEO has established a nonprofit foundation called FundaGeo to support community development activities. LaGEO contributes 20 percent of its budget annually to the foundation, with the option to adjust the budget if more funds are needed to support communities (ESMAP 2023).

Including benefit-sharing elements in procurement documents ensures developers fulfill their commitments to communities and allows governments to align project objectives with their local development plans. In some countries, constitutional or macro-level legal frameworks already facilitate benefit distribution at the regional and/or local level, such as through royalty and licensing frameworks. Similarly, government-implemented policies promoting gender equality and social inclusion have bolstered the participation of women and vulnerable groups in benefit-sharing activities.

For example, Indonesia mandates that all geothermal electricity generation permit holders implement corporate social responsibility (CSR) programs focused on local community development and empowerment through the regional government. These costs are included in the annual work program and budget of the permit holders (ESMAP 2023).

In Kenya, proposed regulations require that revenue from energy resource exploitation be shared equitably among government levels and that investments benefit local communities through profits, training, employment, technology transfer, and CSR programs. However, a clear framework for benefit-sharing mechanisms is still needed (ESMAP 2023). Both KenGen and the Geothermal Development Company have multiple programs benefiting communities.

In Türkiye, all licensees must pay the state a yearly fee equivalent to 1 percent of their income, with 20 percent of this fee allocated to the budget of the local municipality where the project site is located (ESMAP 2023).

Above all, cultivating enduring trust with local communities is paramount. Sustained engagement and transparent information mitigate the risk of costly delays or litigation and may ultimately lead to fruitful partnerships. For example, Baseload Capital has created new revenue streams for rural communities in Japan by partnering with local businesses to enhance economic resilience. Japan has a long history of onsens, or natural hot springs, often accompanied by inns called ryokans. In recent years, many small rural businesses operating these onsens have struggled financially, leading to closures.

Baseload Capital initiated a small-scale pilot project with local business owners eager to continue their traditions. The project utilizes heat from the hot springs to generate electricity. After the hot water is used for power generation, it is supplied to the onsens at a temperature suitable for bathing. This innovative approach not only provides a stable supply of clean electricity and hot water but also creates a new long-term revenue source for onsen owners. Baseload Capital and community members hope that this model of pairing rural tourism with electricity generation can be replicated elsewhere, fostering economic sustainability in rural areas (ESMAP 2023).

Countries with varying levels of geothermal development can benefit from each other’s experiences in project management. A recent successful example involves the exchange of lessons in community engagement between Kenya and New Zealand. Recognizing the opportunity to learn from New Zealand’s successes in engaging communities and respecting sacred geothermal sites, Power Africa, the United States Energy Association, and the Geothermal Energy Association facilitated a partnership between Kenya's state-owned utility KenGen, New Zealand's Contact Energy, and two trusts: the Tauhara North No. 2 Trust and the Ngati Tahu Tribal Lands Trust.

This partnership included four exchange missions, where representatives from New Zealand and Kenya visited geothermal sites in both countries to share ideas and best practices in community engagement and partnership models. Inspired by the lessons learned from New Zealand, KenGen developed a new state-of-the-art community engagement program. Additionally, New Zealand counterparts assisted Maasai community leaders in developing strategic visions, including commercial ventures and social development goals (ESMAP 2023).

Focusing on long-term, high-impact outcomes in benefit sharing is essential for fostering sustainable community development. While infrastructure projects like the construction of a football field may be in high demand and provide immediate benefits, they do not yield the same lasting impact as training or enterprise development programs. These programs build local capacities, enhancing community resilience and independence over time.

For example, in the Philippines, the Energy Development Corporation (EDC), the largest geothermal producer in the country and the third largest globally, has significantly evolved its CSR strategy. Initially, EDC's CSR activities were broad, encompassing health, infrastructure, and education, focusing on what could be given to communities. This approach led to a growing reliance on the company.

Recognizing the need for more sustainable outcomes, EDC shifted its philosophy from transactional philanthropy to transformative empowerment. According to EDC's CSR Lead, the company now prioritizes long-term strategies that protect natural resources while simultaneously contributing to community livelihoods and breaking intergenerational poverty cycles. The focus of CSR activities was narrowed to environmental conservation, education, and social enterprise development. Instead of providing handouts, EDC now equips communities with the tools and capacity to improve themselves.

A prime example of this shift is EDC's environmental conservation program, which has planted over six million trees and restored over 10,000 hectares of land. Beyond environmental benefits, this program has empowered community members to become social entrepreneurs, raising and selling tree seedlings, producing forest-friendly coffee, and leading ecotourism ventures. EDC has supported communities in organizing 121 peoples' organizations, three of which have formalized as cooperatives. These organizations receive business training, assistance in securing operating permits, and initial capital for start-up expenses. This strategic approach underscores the importance of focusing on high-impact, sustainable outcomes in benefit sharing to achieve lasting positive effects (ESMAP 2023).

5. CONCLUSION

When planned effectively, all geothermal projects, regardless of size, can be designed to maximize positive socioeconomic outcomes. These outcomes are critical to all stakeholders, including governments, developers (public and private), operators, and the citizens of the project country, both broadly and at the project site level.

Governments can strategically harness geothermal projects as powerful instruments for economic growth, development, poverty reduction, and social justice. Developing new geothermal projects presents a valuable opportunity to cultivate local industry. There is potential to nurture the growth of domestic companies capable of providing essential goods and services for project development, operation, and maintenance, depending on market readiness. Such companies can often grow to cater to multiple industries. Governments can reap fiscal gains from this industrial growth through income taxes levied on those directly or indirectly engaged in the geothermal sector, and taxes on businesses and goods and services required by the sector. Additionally, the availability of reliable and affordable energy has extensive economic implications. It can act as a catalyst for industrial players to establish local operations and further nurture the growth of small and medium enterprises.

Projects can also be designed to effectively align with local, regional, and national priorities for socioeconomic development, reducing the burden on governments to deliver on these plans independently. For example, the infrastructure developed for a project, such as improved road access, can benefit communities. Developers often pledge to bring additional benefits to communities through other infrastructure projects (e.g., schools, health centers, and drinking water) and socioeconomic development programs (e.g., literacy training and agriculture development programs). With proactive policies in place, governments can ensure the equitable distribution of these benefits among their populations, fostering inclusive prosperity for all.

Optimizing socioeconomic benefits within the project country, particularly the project community, is a pivotal strategy for developers and operators to achieve desired project outcomes. Delivering tangible advantages to the project country, especially to local communities, is a potent risk mitigation tool. It reduces the likelihood of opposition, minimizes conflict management costs, and mitigates the risk of valuable investment opportunities being overlooked. Benefits can include a share of the project's profit and local initiatives to improve the livelihoods of people adjacent to the project.

Collaborating with appropriately consulted local communities offers an opportunity to tap into their knowledge and foster trust and partnerships. This collaborative approach increases the feasibility of projects and helps them remain sustainable in the long term. Publicly listed companies, which are constantly striving to increase their environmental, social, and governance ratings, acknowledge the strategic significance of a robust corporate social responsibility strategy, enhancing their appeal to retail and institutional investors and contributing significantly to their public image.

There are also advantages for developers in developing local supply chains, which will benefit the domestic industry and country. Developing local supply chains can reduce project costs and lead to improved operation and maintenance for geothermal plants over the long term.

Geothermal projects hold the potential to empower citizens. Research estimates underscore the employment impact of geothermal projects. Beyond direct employment, geothermal projects generate indirect jobs in upstream industries and create additional induced jobs through the spending habits of those directly and indirectly involved in the industry. For instance, workers contribute to the local economy during construction by spending a portion of their income within the project community. This, in turn, stimulates additional jobs in the restaurant, retail, transportation, and hospitality industries. The emergence of new employment prospects, particularly in rural and low-income communities, holds the potential for substantial social transformations.

While economic benefits are often more easily quantified, equally significant social benefits encompass new educational opportunities and achievements, skill development, and diversification. Through ongoing community consultations, local communities are given the voice and agency to direct local development and benefit-sharing activities that they feel are needed and most beneficial to their way of life.

At the project site and community levels, infrastructure improvements introduced by developers and/or operators, along with development programs, wield far-reaching socioeconomic impacts, including enhanced mobility, improved health care and education, and increased income generation prospects.

In summary, geothermal projects offer a unique blend of economic, social, and environmental benefits that can drive substantial progress in development and poverty reduction. However, these projects also present challenges that require careful planning and community engagement. By strategically harnessing geothermal energy, governments and developers can foster local industry, create jobs, and improve infrastructure, aligning projects with broader socioeconomic goals. Effective collaboration with local communities ensures that the benefits are equitably distributed, enhancing the sustainability and acceptance of these projects. Ultimately, geothermal energy stands as a powerful tool for achieving inclusive prosperity and long-term development, making it a vital component of a sustainable future.

Keywords: Geothermal Exploration, Risk Mitigation, GREM Program, Indonesia Geothermal Development, Exploration Financing

ABSTRACT

Indonesia is committed to the significant goal of maximizing geothermal energy utilization, necessitating extensive exploration activities. To address the inherent risks, the Indonesian government, in partnership with the World Bank, introduced the Geothermal Resource Risk Mitigation (GREM) program. This facility supports the exploration phase by providing financial mechanisms that de-risk projects.

This study conducts a literature review to assess the challenges confronting geothermal exploration projects in Indonesia. It introduces the key objectives, financing structure, and opportunities provided by the GREM facility. GREM offers risk assessments, technical assistance, and financial support to mitigate the inherent risks of geothermal exploration. This mitigation not only makes geothermal investments more attractive but also improves the bankability of projects and facilitates easier access to financing. The economic analysis is based on published data related to project capital and operational expenditures, revenue projections, financing strategies, and tax treatment.

The paper also includes a project finance analysis to highlight the benefits of utilizing the GREM facility. By employing decision tree with expected monetary value approach, the study evaluates the walk away cost with considering success rate of exploration in hypothetical Indonesian project, comparing scenarios with and without de-risking initiatives.

Our findings indicate that targeted de-risking efforts significantly lower walkaway costs by sharing risks with financiers or the government. The use of de-risking schemes during the exploration stage also reduces the required return from investors, as the associated risks are distributed broader. This study underscores the importance of exploration de-risking application in enhancing geothermal investment. It provides insights for stakeholders aiming to optimize their investment strategies and enhance the resilience of geothermal projects.

1. INTRODUCTION

Indonesia's ambitious plan to significantly expand its geothermal power plant installed capacity is illustrated by the country's target of reaching 5,799 MW by 2030. As of 2023, the installed capacity stands at 2,417.7 MW, highlighting the need for a substantial increase of 3,382 MW over the next seven years. This translates to an average annual addition of 488 MW, a considerable leap from the historical average of 60 MW per year over the past four decades.

The first geothermal power plant in Indonesia, Kamojang-1, was installed in 1983 with a capacity of 30 MW (Darma, Imani, Shidqi, Riyanto, & Daud, Country Update: The Fast Growth of Geothermal Energy Development in Indonesia, 2021; Mansoer & Idral, 2015). Since then, the growth has been steady but slow, utilizing only about 10% of the total geothermal resources. The current pace of development underscores the necessity for massive exploration activities to identify and develop new geothermal resources. Figure 1 shows the historical and target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

To meet the 2030 target, Indonesia should enhance its exploration efforts and adopt comprehensive de-risking measures. Exploration involves identifying viable geothermal resources, which requires significant investment and technological expertise. De-risking strategies, such as the Geothermal Resource Risk Mitigation (GREM) program, are essential to reduce the financial risks associated with exploration and early-stage development.

These efforts will not only accelerate the development of new geothermal projects but also ensure that the projects are financially viable and sustainable. By addressing the exploration and risk challenges, Indonesia can unlock its vast geothermal potential, contributing significantly to the country's renewable energy goals and sustainability target.

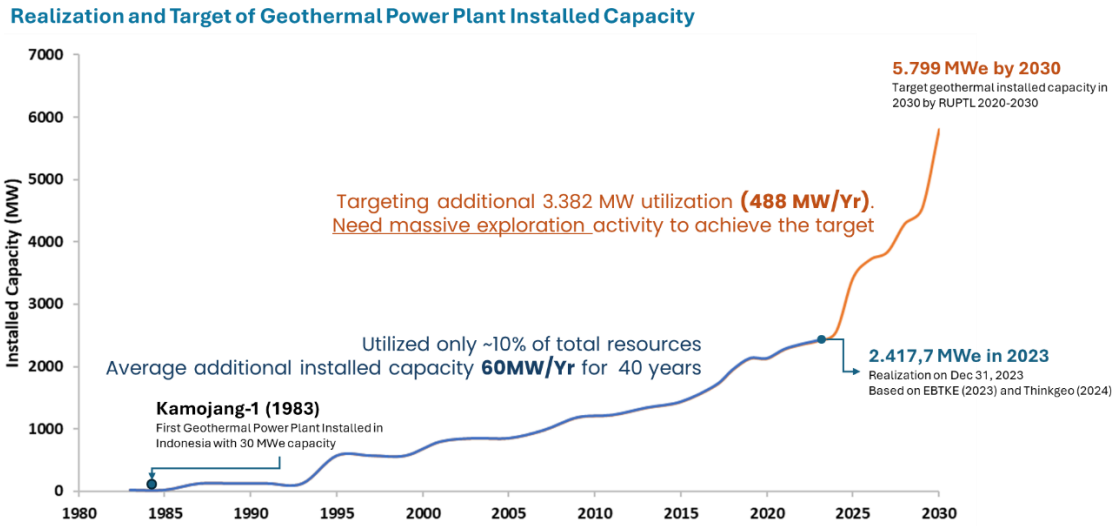

Figure 1: target for geothermal power utilization based on EBTKE (2023) and Thinkgeo (2024).

1.1 Opportunity and Challenges of Geothermal Business

The geothermal sector in Indonesia holds significant market potential, particularly due to the concentration of current reserves in Sumatra and Java, regions with substantial electricity demand. These areas are heavily reliant on coal-fired power plants, which are being phased out under a program initiated by the Government of Indonesia (GoI). This strategic move to reduce coal dependency presents an opportunity for geothermal electricity generation to emerge as a viable substitute (Fadhillah, et al., 2023). Geothermal energy, capable of providing baseload power, is expected to replace coal as the primary source of power generation in Indonesia (World bank, 2011).

Despite its promising potential, the geothermal industry in Indonesia faces significant challenges in attracting investors. The high risks associated with geothermal projects are not adequately compensated by returns, deterring investment. Development projects frequently encounter obstacles during the transition to the production phase, including unfavorable economic conditions, limited resource availability, and social concerns. The industry's progression is influenced by a complex interplay of political, economic, social, and technical (Komendantova, Patt, Barras, & Battaglini, 2012; IRENA, 2022). Figure 2 shows the general problem of Indonesia geothermal project based on Fadhillah (Fadhillah F. R., Economic Evaluation of Bravo Geothermal Prospect in Participating Green Energy Effort, 2023).

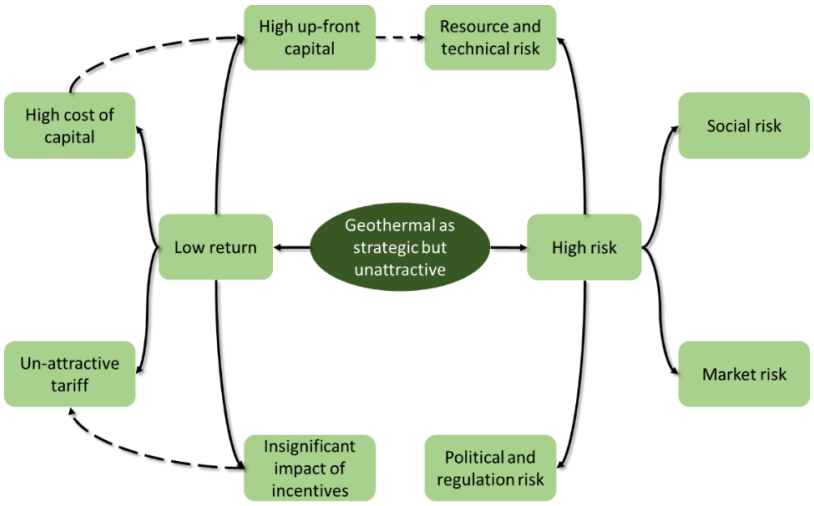

Figure 2: The problem tree of general Indonesia geothermal project.

1.2 Research Question and Objective

The main goal of this study is to assess exploration de-risking program affects the financial viability and attractiveness of geothermal exploration projects in Indonesia. Additionally, the paper introduces the Geothermal Resource Risk Mitigation Program (GREM) as a de-risking facility in Indonesia through a literature review. The research addresses the following questions:

1. What are the major risks encountered by geothermal projects during the exploration stage in Indonesia?
2. How does the mechanism of Geothermal Resources Risk Mitigation program (GREM)?
3. What is the impact of the geothermal de-risking program on project attractiveness from a financial perspective?

2. INDONESIA GEOTHERMAL BUSINESS OVERVIEW

2.1 Indonesia Geothermal Player

Indonesia has 46 geothermal power plants, including expansion units, developed by both State-Owned Enterprises (SOE) and Independent Power Producers (IPP) across 17 geothermal working areas, primarily in Sumatra and Java (Fadhillah F. R., Economic Evaluation of Bravo Geothermal Prospect in Participating Green Energy Effort, 2023; Brilian, et al., 2024). The top three geothermal producers in the country are mainly from the IPP sector. KKOB Star Energy Geothermal Ltd. leads with the highest capacity, totaling 874 MW from just three geothermal fields. PT Pertamina Geothermal Energy (Persero) ranks second, with 677 MW from six fields. Together, these two developers account for half of Indonesia's total installed geothermal capacity. The other half is provided by KKOB Sarulla Operation Ltd., PT Supreme Energy, KS Orka Renewables, PT Geo Dipa Energi (Persero), and PT PLN (Persero).

Notably, KKOB Star Energy Geothermal Ltd. and PT Pertamina Geothermal Energy (Persero) employ different development strategies. KKOB Star Energy focuses on maximizing output from a limited number of fields, whereas PT Pertamina Geothermal Energy manages a larger number of fields, each with relatively smaller capacities.

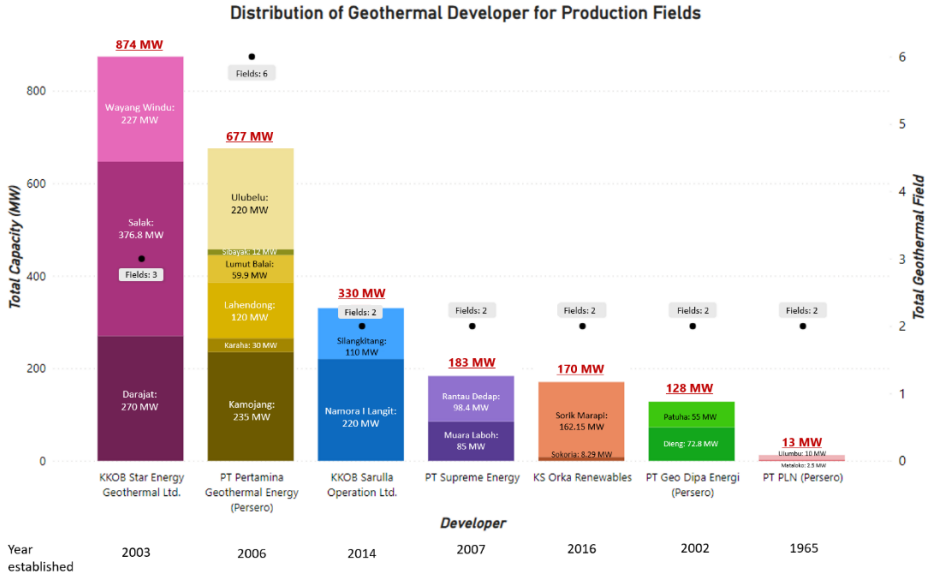

Figure 3: Geothermal player in Indonesia.

2.2 Geothermal Project Stage

The geothermal business process, especially for electricity generation, mainly consisted of preliminary survey, exploration, test drilling, project review, field development, power plant construction, commissioning, and production phases (ESMAP, 2012; IGA, 2014). A geothermal company in Indonesia is eligible to perform preliminary survey until feasibility study for 7 years maximum. The company that successfully reaches commercial operation date (COD) would obtain 30 years of license, Conversely, in cases where an area is found unpromising for geothermal development during the preliminary survey and feasibility study phase, the company is obliged to relinquish the rights to that specific area to the government (Purba, et al., 2021; GoI, 2014). The summary of Indonesia geothermal project stages shown in Figure 4 based on (Fadhillah F. R., Economic Evaluation of Bravo Geothermal Prospect in Participating Green Energy Effort, 2023).

In the exploration phase of geothermal development in Indonesia, the government has launched several initiatives and introduced specific terminologies to support the process. These measures are intended to reduce exploration risks and encourage a favorable investment climate (Apriani, et al., 2023). Below are some of the key government-implemented schemes and terminologies (Table 1):

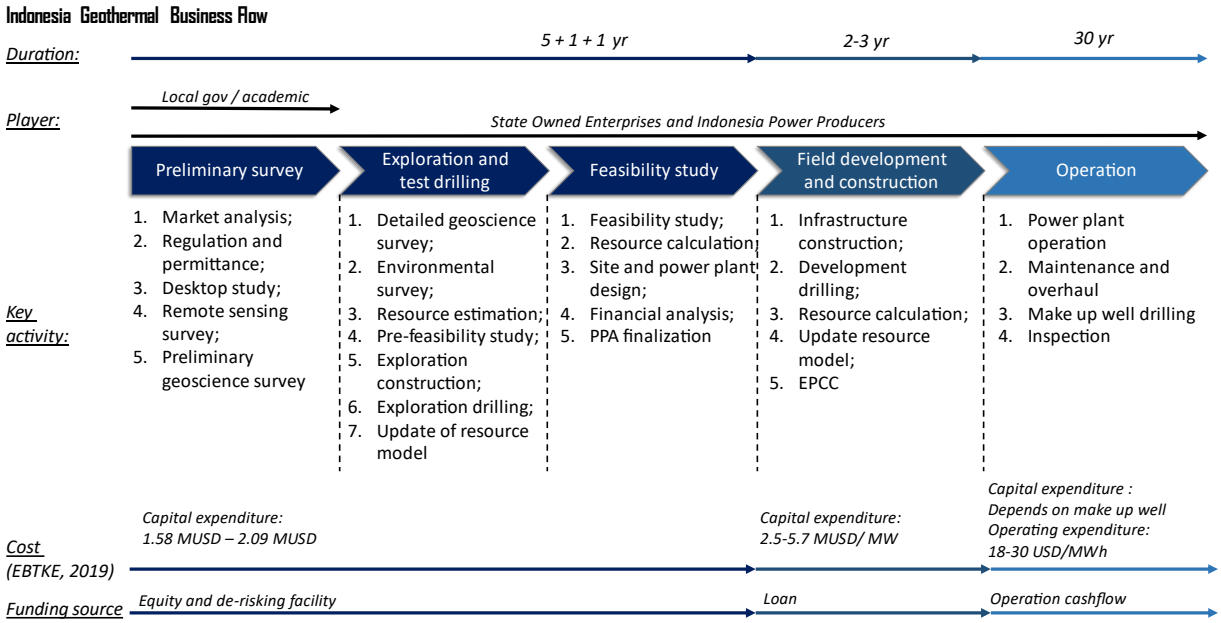

Figure 4: Indonesia geothermal business flow modified from GoI (2014), Purba (2021), and ESDM (2022).

Table 1: Geothermal exploration schemes and terminologies in Indonesia.

***Wilayah Terbuka* (Geothermal Open Area)**	An area suspected of having geothermal potential outside the coordinate boundaries of a Geothermal Working Area
Assignment Area	A Geothermal Open Area with certain coordinate boundaries offered to an Other Party for PSP or PSPE
WKP (Geothermal Working Area)	An area with defined coordinate boundaries used for the exploitation of Geothermal for Indirect Use (power)
***Penugasan Survei Pendahuluan*/PSP (Preliminary Survey Assignment)**	The assignment given by the Ministry of Energy and Mineral Resources to carry out the Preliminary Survey activity
***Penugasan Survei Pendahuluan dan Eksplorasi/PSPE* (Preliminary Survey and Exploration Assignment)**	The assignment given by the Ministry of Energy and Mineral Resources to carry out the activities of the Preliminary Survey and Exploration
***Izin Panas Bumi/IPB* (Geothermal License)**	Permit to conduct exploration and/or exploitation of Geothermal for Indirect Utilization in certain working areas
Government Drilling	Scheme for government to conduct the early stage of geothermal development (preliminary survey and exploration drilling)

In Indonesia's geothermal industry, electricity generation is the primary product and main revenue source. Under common business practices, the steam or electricity is sold to Perusahaan Listrik Negara (PLN), the state-owned electricity company, which is the exclusive buyer. This gives PLN considerable influence in the market, particularly in setting tariffs, which often benefits the company (Fadhillah F. R., 2023). Subsequently, PLN also transmits and distributes electricity to consumers across various sectors, including industrial, commercial, and residential users (Brilian, et al., 2024). This arrangement is known as the on-grid model.

2.3 Geothermal Exploration Challenges

The main objective of geothermal exploration programs is to identify and assess resources that can be economically developed based on exploration findings (Apriani, et al., 2023). However, developers and investors frequently face dilemmas during this stage due to the need for significant upfront capital investment and the reliance on limited, uncertain information about geothermal potential.

Drilling activities and the construction of essential infrastructure, such as access roads and well pads, represent the most substantial costs in an exploration project. The primary challenges in Indonesia's geothermal exploration are summarized below (IGA, 2014; Poernomo A. S., 2015; Darma S. , Indonesia: Vast geothermal potential, modest but growing exploitation, 2016; Umam, Adityatama, & Purba, 2018; Siahaan, Purba, Septiani, &

Paripurna, Preparing Technical and Commercial Documents for Geothermal Exploration Project Financing in Indonesia, 2023):

1. Difficulty in locating the "hottest area": Geothermal resources could not directly be manifested at the surface, necessitating detailed geological, geochemical, and geophysical (3G) surveys and test well drilling. The lack of clear surface indications or thermal manifestations can make it challenging to identify the most promising areas for exploration, leading to an increased risk of drilling dry wells.
2. High exploration costs: The expenses for 3G surveys, developing a reliable conceptual model, and drilling test wells can be substantial. There is always a risk that geothermal projects may not yield viable resources, making it challenging for developers to secure funding for exploration activities due to the high upfront capital and uncertainties involved.
3. Complex geology: Geothermal resources in Indonesia are mainly located in a volcanic area with complex geological environments, making it difficult to understand the subsurface conditions and identify the most promising areas for exploration.
4. Lack of direct and reliable data: In some cases, there may be a need for more data on the geology and geochemistry of an area, making it challenging to identify potential resources and plan the exploration activities.
5. Environmental impacts: Exploration activities can have various environmental impacts, such as air and surface water pollution, soil degradation, hazardous noise, release of hazardous gases, landslides, deforestation, and the potential for groundwater contamination. Mitigating these impacts can be costly and time-consuming.
6. Social and community impacts: Exploration activities can also have social and community impacts, such as displacement of local communities and land-use conflicts. Developers need to address these impacts and engage with local communities to ensure their support and minimize the risk of project delays or cancellations.
7. Uncertain regulations: Geothermal exploration is subject to various national, regional, and local regulations. The uncertainty can make it difficult for developers to navigate the regulatory environment and can increase the risk of project delays or cancellations.

Sanyal et al. (2011) provided statistical data from the Kamojang field in Indonesia, showing an initial drilling success rate of 20-50% for the first six wells. The study highlighted significant fluctuations in success rates as additional wells were drilled, which gradually stabilized during the development phase and exceeded 70% in the operational phase. This data underscores the inherent challenges and uncertainties of geothermal exploration drilling, emphasizing the necessity of effective risk mitigation strategies to improve the overall success rate of geothermal projects.

IFC (2013) reported an average success rate of 50% across 2,613 wells. Notably, success rates improved with subsequent drilling activities, starting at 59% for the first five wells and rising to 71% for the first 30 wells, with this upward trend continuing beyond the 50th well. The dataset for this analysis included both publicly available information and confidential data shared by individual geothermal developers with GeothermEx, Inc. over four decades.

The exploration stage of geothermal development is characterized by the primary risk associated with the uncertainty of identifying economically viable geothermal resources. Recognizing this challenge, institutions within the global geothermal industry have undertaken efforts to develop schemes aimed at mitigating risks for geothermal developers during the exploration phase. Subsequent chapters will delve into an in-depth examination of the various schemes presently employed in the geothermal industry.

2.4 Geothermal Exploration Cost

The cost associated with geothermal exploration in Indonesia can differ widely, depending on the specific aspects of the project and the exploration drilling approach employed. Table 2 offers an estimate of the costs expected for carrying out geothermal exploration drilling, giving a broad view of the financial expenses involved.

This table describes the step-by-step process of an exploration project, highlighting various phases that are undertaken sequentially, starting with attempts to gather data at a lower cost. After the initial collection of data, if the findings suggest a viable geothermal presence, developers may move forward with more substantial investment activities. Noteworthy in Table 2 is the emphasis on the peak of exploration endeavours—the drilling of deep wells, which stands as the most expensive phase of exploration.

The information laid out in the table illustrates a strategic approach to exploration, where early-stage activities with lower costs set the stage for subsequent, more intensive investments. Highlighting the cost differences between phases emphasizes the importance of careful financial planning and decision-making in geothermal

exploration projects. Understanding the financial implications at each phase allows developers to manage their resources and evaluate the economic viability of advancing through the exploration stages.

It is crucial to recognize that the costs presented in Table 2 can vary based on a variety of factors, such as drilling depth and complexity, geological conditions, logistical challenges, and the specific circumstances of the local area. As such, the costs should be viewed as estimates that provide a general guide rather than definitive figures.

Table 1: Cost estimate of geothermal exploration drilling (modified from IGA, 2014; GeothermEx, 2010; Purwanto et al., 2018; Purba et al, 2019; Purba et al., 2020; Adityatama, 2020; Purba et al., 2021).

Activity	Geology survey	Geochemistry survey	Geophysical survey	Initial conceptual integration and well targeting	Exploration drilling
Activity Description	Geological mapping on an area of 400 km^2. The work package including pre-field-work study, rock sampling and identification, structural mapping, and reporting.	Work package including a pre-field-work study, liquid and gas sampling from 30 locations, laboratory analysis and reporting.	Work package including pre-field-work study, 100 MT stations and 150 Gravity stations, interpretations, and reporting.	Integrate all report from 3G surveys to create several scenarios of conceptual models, including peer review.	Using 3 standard/big hole type or 5 slim hole type or combination of 2 slimholes and 1 full-size well. The cost estimate includes infrastructure construction cost to support the drilling operation. The duration estimate includes procurement, preparation, mobilization, drilling, well testing and demobilization.
Duration	4-8 months	4-8 months	4-8 months	3-6 months	18 - 36 months
Cost Estimate (USD)	300,000 – 700,000	200,000 – 400,000	1,000,000 – 2,000,000	100,000 – 200,000	15,000,000 – 50,000,000
Considerations	Accuracy might be affected by terrain, weather, and field personnel experiences.	Accuracy might be affected by sampling method (minimize contamination) and laboratory competences.	Accuracy might be affected by noise during data acquisition and processing method, including personnel interpretation.	Accuracy might be affected by 3G data accuracy and personnel experiences and interpretation.	Allow the exploration team to acquire downhole data directly from the reservoir, which is valuable for more accurate resource assessment but requires higher cost and time than the 3G survey.

3. GLOBAL AND INDONESIA EXPLORATION DE-RISKING SCHEME

A geothermal exploration de-risking scheme is a strategic approach designed to mitigate the financial risks inherent in geothermal exploration projects. The main objective of this scheme is to develop efficient exploration programs that increase the success ratio of exploration activities (Apriani, et al., 2023). ESMAP (2016) and Nur (2023) highlight the importance of exploration de-risking programs as crucial for accelerating and enhancing the development and utilization of geothermal resources.

Government agencies and entities play a pivotal role in mitigating risks associated with geothermal projects, particularly during the exploration phase. This can be achieved through various mechanisms, such as providing financial support, technical assistance, and regulatory oversight. In some instances, governments may act as the sole developer of a geothermal project, assuming all associated risks. Even when development financing is available, the sovereign guarantees typically required mean that the government ultimately bears the risk of project failure. For a government-led exploration program to be effective, it requires an entity with strong in-house expertise, access to appropriate technology, and sufficient financial resources (ESMAP, 2016)

1. **Government drilling** through various mechanisms, such as financial support, technical assistance, and regulatory oversight. In certain instances, governments may even take on the role of the sole developer of a geothermal project, thereby assuming all associated risks. Additionally, when development financing is provided, the requirement for sovereign guarantees often means that the government ultimately bears the risk of project failure. For a government-led exploration program to be successful, it must involve an entity with strong in-house expertise, access to appropriate technology, and sufficient financial resources. (ESMAP, 2016). ESMAP (2016) emphasizes the government led exploration program already executes in 12 countries with 31 projects that equals to 3.613 MW capacity.

2. **Grants and loans, along with cost-sharing arrangements**, play crucial roles in supporting geothermal projects. rants, which are non-repayable funds provided by governments, organizations, or agencies, are often used to fund exploration, feasibility studies, and early-stage development, thereby mitigating financial risks. In contrast, loans are funds borrowed by geothermal developers from financial institutions or governments to cover project expenses. Unlike grants, loans must be repaid with interest over a specified period, increasing the overall costs of the project. (Fadhillah, 2023).

   Cost-sharing arrangements involve distributing project expenses among various stakeholders, such as government entities, private investors, and development agencies. These arrangements help to spread the financial burden and incentivize collaboration, promoting sustainable geothermal development (ESMAP, 2016). effective cost-shared exploration can be achieved through the following strategies:
   a. Government Commitment to Geothermal Expansion: When the government is dedicated to rapidly increasing geothermal generation capacity, it can encourage private-sector involvement by implementing supportive policies.
   b. Attracting Private Investment and Expertise: In situations where the government lacks sufficient geothermal expertise, it is vital to attract private investment and technical knowledge to tap into the country's geothermal resources.
   c. Experience and Selection of Developers: The effectiveness of cost-shared drilling relies on selecting experienced developers through a transparent process with clear criteria, including their willingness and capability to invest risk capital in exploration drilling.
   d. Ensuring Project Continuity: Beneficiaries of cost-sharing funds should be committed to fully developing the project through all subsequent stages until it becomes operational, rather than transferring development rights to other investors after receiving cost-sharing benefits. This ensures the project's continuity and successful completion.

3. **Loan guarantees** serve as a form of financial assurance for lenders, ensuring that if a project encounters unforeseen difficulties or defaults, the guaranteed portion of the loan will be covered by the government or specific financial institutions. This mechanism reduces perceived risks for lenders and encourages them to offer more favorable lending terms to project developers (Apriani, et al., 2023).

Table 3 provides a comparison of various exploration financing facilities utilized in different countries around the world. A detailed comparison of each of these facilities will be presented in a separate table at the end of this paper based on Apriani (2023).

3.1 Indonesia Practice

Indonesia has implemented four geothermal resource risk mitigation schemes. These include government-sponsored exploration drilling (GEUDP), government-led exploration drilling, cost-sharing funding facilities for both public and private developers (GREM), and specific SOE drilling facilities.

a. **The Government-sponsored exploration drilling, executed in partnership with the World Bank through the Geothermal Energy Upstream Development Project (GEUDP),** utilizes funds from both the World Bank and the Indonesian government (via the PISP fund) to finance from 3G surveys to exploration drilling. Initially, SMI led these activities, later transitioning to PT Geo Dipa Energi (Persero) or GDE as the executing body. Once an exploration area is proven viable for geothermal development,

it is to be put up for tender, along with the geothermal data package acquired during exploration drilling. If a developer wins the bid for the geothermal working area explored under GEUDP, they will be required to pay some form of fee or reimbursement.

b. **Government-led exploration drilling, which is implemented by Geological Agency**. In contrast with the GEUDP, where the government only sponsors the exploration activity through the funding via PISP fund, in this scheme the Government through Geological Agency (Badan Geologi) also conduct the exploration surveys and drilling. The Government Drilling by Geological Agency is fully funded by State Budget (APBN), in contrast with GEUDP which has some funding from the World Bank. Should the result be promising, the geothermal working area is then put up for tender. However, unlike the GEUDP scheme, the developer winning the concession is not required to reimburse or pay success fee for the exploration drilling.

c. **The Exploration drilling funding facility for public developers and private developers, facilitated by the World Bank's Geothermal Resource Risk Mitigation (GREM) project**, is designed to reduce financial risks in geothermal exploration. It supports both public and private entities by offering up to USD 30 million per project, with a distinctive feature of risk-sharing that allows for partial repayment for unproductive exploration. In addition to financial support, GREM includes a component for technical assistance and capacity building, enhancing the competencies of key stakeholders in geothermal development.

d. **Exploration drilling funding facility for SOE (SOE Drilling Facility).** The SOE Drilling Facility mirrors the GREM Public Window in structure but relies solely on PISP funding. It also caps funding at USD 30 million per project, offering a mix of loans and risk mitigation support exclusively for SOEs.

These aforementioned schemes are at various stages of implementation, with ongoing projects but no final outcomes yet, making it challenging to assess their effectiveness fully from actual results. The summary of the current risk mitigation schemes in Indonesia and the impact on geothermal development in Indonesia is shown in Table 4.

Table 3: Comparison of Various Exploration Financing Support in Various Countries.

Country	Government led exploration	Grants / loan and cost sharing	Loan guarantee
Turkiye	Government led exploration	Risk sharing mechanism	-
New Zealand	Government led exploration	-	-
East Africa	-	1. East Africa Rift Geothermal Development Program 2. Africa Geothermal Risk Mitigation Program	-
United States	US DOE through national laboratories.	1. User Coupled Confirmation Drilling Program (UCDP) 2. American Recovery and Reinvestment Act (ARRA)	1. Geothermal Loan Guarantee Program (GLGP) 2. Loans for Geothermal Reservoir Confirmation Program
Indonesia	1. Geothermal Energy Upstream Development Project (GEUDP) 2. Government Drilling through Geological Agency	1. Geothermal Resource Risk Mitigation Project (GREM) 2. State Owned Enterprise (SOE) Drilling	1. Sovereign guarantee

Table 4: Summary of the current resource risk mitigation scheme in Indonesia.

Risk Mitigation Scheme	Main Features / Benefit	Current Progress	Impact on Geothermal Development in Indonesia
GEUDP **Year starts of the program: 2017**	Increase success rate for developer's exploration as the bidders can use real	WB withdrew its financing for the geothermal exploration in Wae Sano due to lack of community acceptance in the area. This happened prior any	Due to indefinite delays in the drilling at Wae Sano and the recent commencement at Jailolo, it is currently not possible to assess the actual impact of the GEUDP on

Risk Mitigation Scheme	Main Features / Benefit	Current Progress	Impact on Geothermal Development in Indonesia
	resource information obtained by drilling. Reduces the number of wells to be drilled to reach required MW. Shorten the developer's exploration duration. Reduce cost of equity. Increases the successful of concession tender on resource proven project.	wells have been drilled in Wae Sano. The Government of Indonesia then decided to continue Wae Sano outside the GEUDP program. The current project ongoing under GEUDP program is Jailolo, in which the 3G survey has been done and currently in progress of exploration drilling preparation.	geothermal development in Indonesia. The theoretical impact of the GEUDP program on geothermal tariffs will be discussed in later sections.
Government Drilling by Geological Agency **Year starts of the program: 2019**	Increase success rate during further exploration drilling by developer if the Geological Agency's drilling success to find economic geothermal resource. Potentially reduces the exploration duration. Increases the successful of concession tender on resource proven project.	Drilling in Cisolok failed to reach the targeted 2,000 mMD depth well, and was only able to reach 806 mMD in CKK-1A. The second well (CKK-2) was not drilled due to the significant cost overrun in drilling in the first well. Drilling in Nage was significantly longer than initial plan. NGE-01A reached 1,500 mMD after 175 days, while the NGE-02 only reached 600 mMD before experiencing stuck pipe and then abandoned. NGE-01A drilling result shows high temperature (260 degC), but no permeability. To date, only Nage that has been put to tender by EBTKE.	Although Nage was put up for tender in 2022 and retendered in 2023, the response has been lackluster, with Pertamina Geothermal Energy (PGEO) withdrawing from the tender process. Interviews with several geothermal developers revealed that some companies believe the resource areas in Cisolok and Nage have not been sufficiently derisked. This is attributed to the failure to reach total depth (TD) and to identify economically viable geothermal reservoirs in both areas.
GREM **Year starts of the program: 2020**	Provides loan for exploration and delineation. Reduce walkaway cost or cost of failure. Reduce cost of equity.	The application for GREM facility is currently ongoing for two Public Window exploration projects. The technical proposals from the developers are currently being reviewed prior deciding whether to continue the process or not. From the Private Window, so far there are three developers that have signed the NDA. There are a total of four geothermal fields that are in Preliminary Assessment by SMI from the Private Window application.	So far, no drilling has been funded by GREM, but four developers (one SOE and three private) have signed NDAs with SMI to initiate GREM funding applications for seven exploration fields. This suggests that the funding facility's partial repayment or forgiveness options are appealing to developers, potentially boosting private investment in Indonesia's geothermal exploration.
SOE Drilling	Similar to GREM.	GDE has submitted the technical proposal for SOE Drilling funding facility for	Currently, only one exploration field owned by a state-owned enterprise has begun the application

Risk Mitigation Scheme	Main Features / Benefit	Current Progress	Impact on Geothermal Development in Indonesia
Year starts of the program: 2020	Provide loan for exploration. Reduce walkaway cost or cost of failure. Reduce cost of equity.	Candradimuka field. The technical proposal is currently being reviewed by SMI.	process for SOE drilling funding. The process is still in its early stages, making it premature to evaluate its overall impact on Indonesia's geothermal development.

4. GEOTHERMAL RESOURCE RISK MITIGATION PROGRAM (GREM) IMPLICATION TO PROJECT

4.1 GREM Mechanism

The Geothermal Resource Risk Mitigation (GREM) facility, established by Sarana Multi Infrastruktur (SMI) in collaboration with the World Bank, is designed to mitigate risks associated with geothermal exploration projects. The primary objective of GREM is to expedite investment in Indonesia's geothermal sector by providing financial support for upstream resource development. This support is particularly focused on exploration and delineation drilling, which are essential for resource confirmation. The facility offers a debt package to geothermal developers who have already secured a working area and conducted preliminary surveys, thereby facilitating critical exploration and delineation drilling activities.

This facility is crucial because conventional debt and financing sources are typically reluctant to fund exploration drilling due to the high levels of uncertainty and risk involved. In contrast, GREM provides the necessary financial support for exploration drilling to confirm the presence of sufficient productive steam resources for power generation. Once the resource is confirmed as sufficient, developers can proceed with the project using commercial project finance for exploitation drilling and power plant development. Consequently, GREM not only facilitates the initial stages of geothermal development but also boosts confidence among other financial institutions, making them more likely to fund subsequent development stages of the pertinent working area. (Siahaan, Purba, Septiani, & Paripurna, 2023; Siahaan, Septiani, Purba, & Paripurna, 2023; SMI, 2021).

Siahaan et al (2023) emphasize the unique feature of GREM, which is the availability of a de-risking facility in the event of exploration failure. This feature ensures that the developer does not fully bear the risks and costs associated with exploration. According to SMI (2021), this facility provides a form of “forgiveness” for each project, allowing the developer to repay only a portion (up to 50%) of the total facility in the event of exploration and/or political risk:

1. Exploration Risk: This involves the possibility that despite completing all drilling activities and adhering to the exploration cost budget as specified in the work plan, an independent assessment of the geothermal data and information concludes that the exploitation and/or utilization stage in that area is not feasible.
2. Political Risk: This occurs when government actions, based on applicable laws and regulations, halt the implementation of activities specified in the work plan and exploration cost budget.

Based on MoF Regulation No. 80/2022 Article 34, financing provided by PT SMI to public developers may include a risk-sharing mechanism that allows for forgiveness of up to 50% of the total facility in the event of exploration and/or political risks. GREM incorporates this risk-sharing mechanism, enabling developers to receive partial repayment of the facility (up to 50% of the total facility limit) in the case of unsuccessful explorations. Consequently, the GREM facility offers crucial early-stage support, helping to mobilize downstream financing from commercial and other financiers on a larger scale.

Table 5 provides a comparison of various exploration financing support in Indonesia and other countries particularly facility supports that are intended to the public and private geothermal developers as explained above. Due limited information on the geothermal de-risking facility, the comparison will not include United States and New Zealand geothermal exploration de-risking scheme based on Apriani (2023).

4.2 GREM IMPACT TO PROJECT ATTRACTIVENESS

4.2.1 Reduction in walkaway cost

The program significantly reduces the walkaway cost for developers in the event of failed exploration, thereby mitigating one of the primary financial risks associated with geothermal projects. Walkaway cost refers to the sunk costs that developers must absorb when an exploration project does not yield viable geothermal resources, often leading to substantial financial losses.

By reducing the walkaway costs, GREM effectively lowers the financial risks associated with unsuccessful geothermal exploration. This encourages more developers to enter the geothermal sector, knowing that their potential losses are mitigated through the risk-sharing mechanism. Furthermore, this reduction in financial risk makes geothermal projects more attractive to investors.

Figure 5 shows the simulation using decision tree with economic monetary value for GREM facilities. Under the GREM program, developers receive partial forgiveness of up to 50% of the exploration costs in the event of failure. For instance, in a typical exploration project with a total cost of 40 million USD, GREM covers 30 million USD of this amount. If the exploration is unsuccessful, GREM forgives 15 million USD of the drilling costs, significantly lowering the financial burden on developers. This significant reduction means that developers are more likely to undertake geothermal exploration, knowing that their potential financial losses are mitigated by the GREM facility. This not only makes geothermal projects more financially viable but also more attractive to investors who are typically risk-averse.

Table 52: Comparison of Various Exploration Financing Support in Various Countries (Siahaan et al, 2023).

Parameter	GREM Public Window (Indonesia)	GREM Private Window (Indonesia)	RSM (Turkey)	GRMF (East Africa)
Source of Funding	A combination of Multilateral Funds (channeled through the IBRD) and Geothermal Fund from the Indonesian Government	Multilateral Funds (channeled through the IBRD)	Clean Technology Fund (CTF)	German Federal Ministry for Economic Cooperation and the European Union (EU) - Africa Infrastructure Trust Fund through KfW Entwicklungsbank (KfW)
Eligible Beneficiary	Public geothermal developers (SOE/ majority owned by SOE developers)	Private geothermal developers	Private geothermal developers	Public developers, private developers, and Public Private Partnership (PPP)
Type of Facility Support	Loan with de-risking feature	Loan combined with subscription of Financial Instrument(s) issued by the private developers	Reimbursable Grant	Grant
Facility Limit	75% of the approved Total Drilling Program Costs with cap at maximum USD 30 million per project	75% of the approved Total Drilling Program Costs with cap at maximum USD 30 million per project	Maximum USD 4 million per project	- Infrastructure grants: up to 20% of the costs for infrastructure required for surface studies and drilling programs. - Surface study grants: up to 80% of eligible costs for surface study (excluding infrastructure costs). - Drilling grants: up to 40% of cost of exploration drilling and testing programs for reservoir confirmation wells (excluding infrastructure costs). - Continuation Premium: up to 30% of the approved costs of continuation activities or up to 30% of the developer's share of

Parameter	GREM Public Window (Indonesia)	GREM Private Window (Indonesia)	RSM (Turkey)	GRMF (East Africa)
				the eligible costs incurred. during the initial drilling, whatever is lower.
Eligible Expenditures	- Surface Studies (only for legacy financing) - Exploration drilling - Well-Testing	- Exploration drilling - Well-Testing	Exploration drilling (infrastructure costs shall not be included). Depending on the project location, exploration study costs may be eligible	- Surface studies - Exploration drilling and well testing
Facility Disbursement Scheme	- The disbursement schedule is discussed and agreed between PT SMI and the beneficiary during loan negotiation. - Every disbursement request will require the beneficiary to qualify that they are within an acceptable bound of the pro-forma budgets. - All disbursements must result in debt-to-equity ratio being maintained of not more than 75:25	- The disbursement schedule is discussed and agreed between PT SMI and the beneficiary during loan negotiation. - Every disbursement request will require the beneficiary to qualify that they are within an acceptable bound of the pro-forma budgets. - All disbursements must result in debt-to-equity ratio being maintained of not more than 75:25	Reimbursement of actual Acceptable Well Cost (AWC) incurred by the license holder.	Disbursement of grant funding based on project milestones and achievement of specified targets.
Repayment Obligation of the Beneficiary	Principal and interest with potential principal forgiveness if the exploration is unsuccessful	Principal and interest with potential principal forgiveness if the exploration is unsuccessful	5 (five) percent of success fee of the Acceptable Well Cost (AWC) if the exploration is successful	Grant funding, no repayment obligation

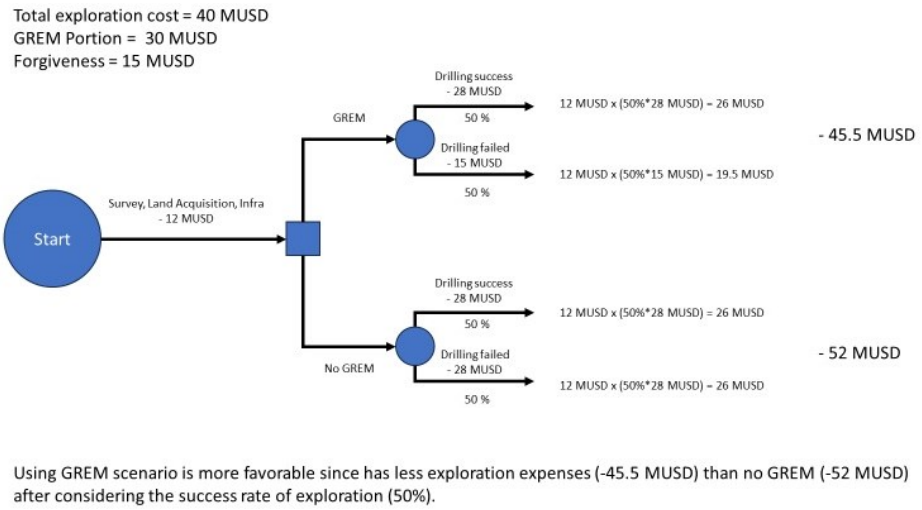

Figure 5: simulation using decision tree with economic monetary value for GREM facilities.

4.2.2 Risk sharing led to lower required return

The reduced risk associated with GREM-backed projects directly impacts the cost of equity. Typically, geothermal projects face high costs of equity due to the inherent uncertainties and risks involved, especially during the early exploration stages. However, with the GREM program sharing these risks, the perceived risk by investors is lower, which leads to a decrease in the required return on equity. According to GT Management (2020), the cost of equity is assumed to decrease to 12.5% for State-Owned Enterprise (SOE) developers and 15% for Independent Power Producers (IPP) developers, as opposed to higher rates typically associated with greenfield projects.

This reduction in the cost of equity translates into a lower discount rate used in Net Present Value (NPV) calculations, thereby enhancing the project's NPV. A lower discount rate means future cash flows are valued higher, which improves the overall financial attractiveness of the project. Investors are more likely to commit funds to projects with higher NPVs, which makes GREM-backed geothermal projects more competitive in the market.

5. CONCLUSION

The Geothermal Resource Risk Mitigation (GREM) program, introduced by the Indonesian government in partnership with the World Bank, plays a crucial role in enhancing geothermal energy utilization in Indonesia by addressing the significant risks associated with exploration activities. This study highlights the challenges faced by geothermal exploration projects and demonstrates how the GREM facility provides comprehensive support through risk assessments, technical assistance, and financial mechanisms. The economic analysis and project finance evaluation reveal that targeted de-risking efforts significantly reduce walkaway costs and lower the required return from investors by distributing risks more broadly. These findings emphasize the importance of de-risking initiatives in making geothermal investments more attractive and bankable. The study provides valuable insights for stakeholders to optimize their investment strategies and improve the resilience and financial viability of geothermal projects in Indonesia.

Keywords: multi-actor analysis, PESTLE, policy; geothermal energy, Indonesia

ABSTRACT

The Indonesian government has prepared a road map for Net Zero Emissions (NZE) in the energy sector by 2060. The government is committed internationally to reducing greenhouse gas emissions as part of its Nationally Determined Contributions. This paper presents a comprehensive analysis of geothermal development through multi-actor analysis and a political, economic, social, technological, legal, and environmental (PESTLE) analysis and policy analysis approach by reviewing the most up-to-date relevant literature. This study focuses on multi-actor analysis in geothermal development through the actors, interests, authorities, and regulations in regulating the geothermal activities of each actor. The results show that geothermal energy development involves stakeholders, policies or regulations, institutions, technology, and other interconnected and changing elements. Based on the results of stakeholder analysis and policy analysis, the Ministry of Environment and Forestry (MEF) and the Ministry of Finance (MF) are key stakeholders in geothermal development. To encourage geothermal development to achieve the NZE 2060 target, MEF can do this by facilitating Environmental Approval and licensing in conservation forest areas and encouraging geothermal development in conservation forest areas by changing the function of the Nature Reserve Forest Area into a Nature Conservation Area with utilization zones/blocks. Meanwhile, MF can encourage geothermal development by providing fiscal and non-fiscal facilities to improve the economics of geothermal projects.

1. INTRODUCTION

Geothermal energy development is a dynamic and complex process involving stakeholders, policies or regulations, institutions, technology, and other interconnected and changing elements (Vidal & Marle, 2015; Yudha et al., 2021). This complexity increases the challenges for the government in achieving these goals. A systematic and holistic approach is needed to understand the complexity of geothermal energy development. Understanding the relationship between the elements involved in developing the geothermal energy sector is becoming increasingly important and necessary to develop long-term strategies to encourage the development of the geothermal energy sector (Yudha et al., 2022). Geothermal development is a complex matter because it is surrounded by many external factors which often create uncertainty and hinder its development. Project scale, interrelationships, regulations, context, permits, and project stage contribute to the complex nature of geothermal development (Vidal & Marle, 2015).

ESMAP divides geothermal development into several stages: preliminary survey, exploration, well testing, project planning and review, field development and drilling of production and injection wells (exploitation), construction, start-up, commissioning, and operation and maintenance. Full-scale geothermal development projects typically take 5 to 10 years to complete. Due to the long development cycle of these projects, GPP is not a quick fix to a country's electricity supply problems. However, it must be part of a long-term electricity generation strategy (Gehringer & Loksha, 2012). Geothermal has advantages compared to other power plants, namely that it is a clean, environmentally friendly, and renewable energy source, does not require large areas of land, and does not have a significant impact on the environment because it implements a closed cycle, namely that geothermal fluid that has been utilized into electrical energy will be injected back into the in the bowels of the earth. Apart from that, geothermal energy has other advantages, namely that it is free from the risk of fluctuations in primary energy prices, does not depend on the weather, and can only be used to provide local energy so that it can be used as capital for national energy security.

Therefore, this research is interested in examining multi-actor and PESTLE research as an approach to developing a Geothermal Power Plant (GPP) in Indonesia. This literature review will map the challenges and opportunities in developing sustainable GPP. The study began by mapping stakeholders in geothermal development, studying the literature on mapping regulations and stakeholder authority from a sustainable perspective, and identifying indicators used to measure the interest or performance of stakeholders in geothermal development in Indonesia.

3. RESEARCH METHODOLOGY

3.1 Case Study: Geothermal Development in Indonesia

Identifying, mapping, and analyzing the dynamic relationships between each level are essential pillars of a multi-level perspective framework in Indonesia's geothermal energy development transition process. The actors involved in the geothermal energy transition in Indonesia are energy providers, the Indonesian National Electricity Company, and consumers (Wisaksono et al., 2018). Geothermal resource development projects in Indonesia can be categorized as public-private partnerships, where business relationships are formed between private companies and government institutions to implement electricity supply projects. The problem of geothermal development in Indonesia is also greatly influenced by infrastructure conditions, such as road access, transportation modes, and high-voltage electricity transmission that will be used to supply electricity produced by GPP (Yudha et al., 2022).

The Indonesian Government has committed to contributing to preventing climate change and rising global temperatures through the 21st Conference of Parties (COP) of the United Nations Framework Convention on Climate Change (UNFCC) in 2015, better known as the Paris Agreement to reduce emissions by 29% by own efforts and become 41% with international cooperation by 2030. The Indonesian Government's commitment was later ratified by the Paris Agreement on the United Nations Framework Convention Concerning Climate Change. This commitment to climate change aligns with the Indonesian Government's commitment to the seventh Sustainable Development Goal (SDGs), namely ensuring access to affordable, reliable, sustainable, and modern energy for all. The global target for 2030 for renewable energy is to substantially increase the proportion of renewable energy in the worldwide energy mix. As a national energy policy guideline to provide direction for national energy management to realize energy independence and national energy security to support sustainable national development, the Indonesian Government sets a renewable energy mix of 23% of the primary energy mix in 2025 and 31% in 2050.

To increase the electrification ratio, support the achievement of renewable energy mix targets, and reduce greenhouse gas emissions, it is necessary to develop electricity infrastructure, especially power plants sourced from renewable energy. In the PLN Electricity Supply Business Plan (RUPTL) for 2021-2030, electricity generation sourced from renewable energy is targeted at 20,923 megawatts or the equivalent of 51.6% of the total electricity generation and renewable energy mix for electricity generation in 2025 is targeted at 23%. The additional capacity of the GPP in the PLN RUPTL 2021-2030 is targeted at 3,355 megawatts. The Indonesian government has prepared a road map for NZE in the energy sector by 2060. It is hoped that GPP capacity can increase significantly from 2,200 megawatts in 2021 to 5,500 megawatts in 2030 and 22,000 megawatts in 2060. Indonesia has enormous potential geothermal resources, and their locations are spread along the active volcanic route (ring of fire) starting from Sumatra, Java, Bali, Nusa Tenggara, North Sulawesi, and Maluku. Based on the Regional Distribution Map and Indonesian Geothermal Resources in 2023, Indonesia's geothermal resources are 23,591.8 megawatts. However, the use of geothermal energy for electrical energy in 2024 will only reach 2,597.51 megawatts or 11% of the total geothermal resources.

Even though the potential is enormous, there are still many obstacles that hinder the optimal use of geothermal energy, both from technical and non-technical aspects, including high-risk geothermal exploration, geothermal locations in conservation areas, pricing mechanisms, infrastructure that has not yet been built which affects geothermal development, power wheeling, and community resistance. One of the biggest obstacles in developing geothermal energy lies in the early stages of upstream geothermal projects, namely the exploration stage. Geothermal resource development projects in Indonesia can be categorized as public-private partnerships (PPP), where business relationships are formed between private companies and government institutions to implement electricity supply projects. The problem of geothermal development in Indonesia is also greatly influenced by infrastructure conditions, such as road access, transportation modes, and high-voltage electricity transmission that will be used to supply electricity produced by GPP (Yudha et al., 2022).

3.2 Methodology

Several methods are available to support actor analysis. The basic procedure covers six steps: formulation of a problem, inventory of the actors involved, exhibiting the formal chart, determining the actors' interests, mapping out the interdependencies between actors, and determining the consequences of these findings (Enserink et al., 2022). PESTLE analysis is often used to uncover problems and discourses that are primarily qualitative, making them difficult or unsuitable to be resolved quantitatively. In particular, it can be used to holistically analyze and describe various problems. PESTLE analysis has recently been applied to specific industrial sectors, such as the conventional energy industry, fossil fuels (Climent Barba et al., 2016; Yudha et al., 2018), and renewable energy (Islam & Mamun, 2017; Mytilinou et al., 2017).

Using PESTLE analysis, new strategic policies can be developed to replace and update policies that are no longer effective or efficient. PESTLE analysis can also be used to monitor macro or external environmental factors that play a role in impacts on the environment. Political analysis looks at the extent and impact of state power on the

economy. For example, specific environmental policies may impose sanctions on companies that cannot comply. Economic factors directly impact economic capacity, organizations, industrial/market sectors, and nation-states. Social factors examine the social context of these institutions, including, but not limited to, population analysis, demographics, and cultural trends. Technological factors relate to technological progress, including research and development (R&D), specialized technology, and automation. Legal factors consider laws and policies, including consumer protection laws, safety standards, and employment laws. Environmental factors are all critical factors conditioned or influenced by environmental problems, geographical location, global climate change, weather, et cetera (Yudha & Tjahjono, 2019). This research uses multi-actor analysis and PESTLE as the approach. Stakeholder analysis is a simple tool whose proper use may be expected to develop in accuracy and value as analysts gain experience, especially learning to recognize stakeholders and stakes from having seen the like before in other projects. PESTLE analysis is a framework or tool commonly used in business management to analyze the environment in which they operate or plan to launch new operations.

The geothermal project development for the case study was mapped, and the actors for various stages were analyzed. An actor analysis covering six steps was performed to characterize the development of the geothermal project. As shown in Figure 1 and Figure 2, one of the preliminary steps is the literature review.

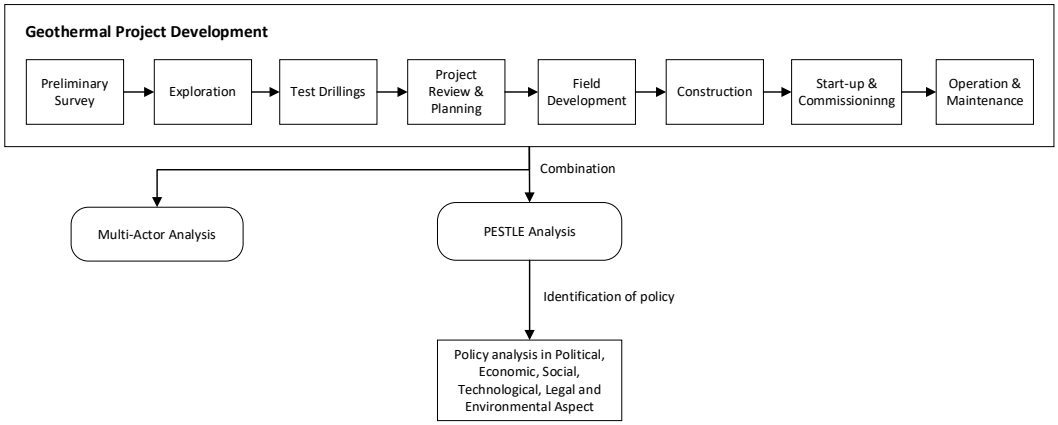

Figure 1: Concept of multi-actor analysis and policy analysis for the geothermal development.

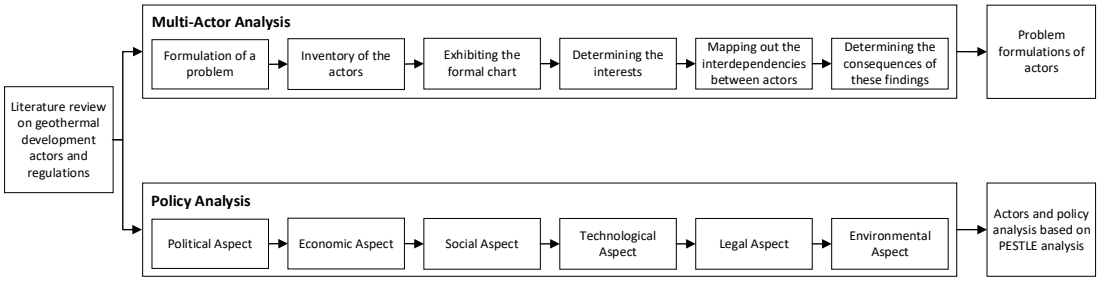

Figure 2: Research methodology.

4. RESULT AND DISCUSSION

4.1 Multi-Actor Analysis

A complex policy structure surrounds the geothermal industry, with multiple actors holding conflicting powers and agendas. The stakeholder structure consists of ministries, local governments, PLN, IPP, and PT SMI, a state-owned enterprise that the Ministry of Finance has assigned to manage PISP funds. The policy structure surrounding the geothermal industry in Indonesia is shown in Figure 3.

Based on the multi-actor concept seen from various points of view, namely perceptions of problems, goals, interests, root causes, resources, and positions based on policies in geothermal development in Indonesia, there is a perspective of perception and goals of each actor who has different interests. Ministries or institutions involved in geothermal development have different perceptions and points of view, so it needs to be mapped out from the policy aspects of each ministry or institution so that geothermal development in Indonesia can be encouraged to achieve the energy sector's NZE target by 2060, a multi-actor analysis of geothermal development is shown in Table 1. From various actors' perceptions of existing problems, it turns out that all actors related to the geothermal industry have a common interest, namely joint efforts to optimize geothermal utilization and encourage the achievement of the target of increasing the installed capacity of GPP.

Table 1: Multi-actor analysis of geothermal development in Indonesia.

Actor	Problem Perception	Objective(s)	Interest(s)	Cause of Problem	Resources	Position
Ministry of Energy and Mineral Resources (MEMR)	Increasing the contribution of GPP to the national energy mix in the energy transition of the electricity sector.	Increasing the development of GPP to support Indonesia's NZE target in 2060.	Accelerating the development of GPP to reduce carbon emissions.	GPP is renewable energy that can be used as a baseload in the electricity system and contribute to reducing carbon emissions.	Authority to regulate geothermal business activities and determine electricity rates from GPP.	Ensure that the percentage of geothermal utilization for the national energy mix increases and reduces carbon emissions.
Ministry of Finance (MF)	The increasing need for incentives is due to the capital-intensive nature of geothermal projects with high risks.	Encourage geothermal project investment programs to increase national geothermal production.	Attracting investors in GPP to encourage national economic growth.	Investing in GPP projects requires high capital and uncertainty at the exploration stage.	Authority to regulate exemption from import duties and non-collection of taxes on import goods for geothermal operations.	Ensure support for fiscal incentives to increase geothermal utilization to reduce carbon emissions.
Ministry of Agrarian Affairs/Land and Spatial Planning (MAA/LSP)	Spatial planning to create a sustainable space for geothermal business activities.	Suitability of national, provincial, district/city spatial planning that accommodates detailed spatial planning for constructing GPP.	Providing legal certainty in implementing spatial planning, including business and geothermal business activities.	The spatial plan is the basis for the Environmental Approval requirements for geothermal business plans and activities.	Authority to prepare and determine detailed national spatial planning plans as a reference for provincial/ regency/city plans and permits in the rural/land and spatial planning sectors.	Ensure spatial planning support for the construction of GPP.
Ministry of Environment and Forestry (MEF)	We are increasing the need for environmental protection and management for geothermal activities.	Suitability of geothermal business plans and activities to mitigate impacts on the environment.	Use of renewable energy and GPP to reduce carbon emissions in Indonesia	GPPs are renewable energy that have low carbon emissions and are environmentally friendly	The authority to determine Environmental Approval for geothermal activities is an activity that requires an analysis of environmental impacts (AMDAL) or environmental management efforts and ecological monitoring efforts (UKL-UPL).	Ensure the achievement of greenhouse gas emission reduction in the energy sector by using renewable energy, especially GPP.
	Increasing carbon emissions, deforestation rates, and the need to develop renewable energy from	Regulate the use of some forest areas for development outside forestry activities, which have inevitable	Encourage using environmentally friendly GPP in protected forests, production forests, and	There is an increased need for forestry land to construct GPP projects whose prospect areas are in	Authority to determine Forest Area Use Approvals for geothermal business activities located in protected forests, production forests, and	Ensure the use of protected forest areas or production forests for geothermal power generation activities

Actor	Problem Perception	Objective(s)	Interest(s)	Cause of Problem	Resources	Position
	environmentally friendly GPP.	strategic objectives, including constructing GPP.	conservation forest areas.	protected forests, production forests, and conservation forest areas.	conservation forest areas through the Online Single Submission (OSS) system.	without changing the primary function of the forest area by considering specific area and time limits as well as environmental sustainability.
Ministry for Public Works and Human Settlements (MPWHS)	Increased allocation of regional road infrastructure needs to overcome constraints and obstacles in supporting the development of GPP.	Accelerate the improvement of regional road connectivity to provide maximum benefits and encourage infrastructure activities for GPP.	Providing accessible regional road infrastructure with good road conditions to support GPP infrastructure activities.	The GPP developer's site is in a remote area with inadequate infrastructure that requires increased road stability.	Authority to carry out regional road construction activities and help improve the stability of roads for constructing GPP infrastructure.	Improving the quality of roads and bridges to support GPP infrastructure activities.
	Allocation of water resources to support geothermal exploration and exploitation activities.	Realizing the orderly implementation of permits for using water resources for exploration well drilling and geothermal exploitation activities.	Providing water resources for geothermal exploration and exploitation activities by establishing priorities.	When exploration well drilling and geothermal exploitation activities take place, there is an increased need to use water resources as a medium and material.	Authority to determine technical recommendations and permits to use water resources for geothermal exploration and exploitation activities.	Ensure that water resources can be used for geothermal exploration and exploitation activities.
Ministry of Internal Affairs (MIA)	The initial stages of geothermal development at GPP project locations in the region and the local community present many obstacles.	Encourage orderly support for the implementation of geothermal activities within the regional government.	Encourage ease of licensing, incentives, and guaranteed land availability for geothermal business activities within the local government.	The construction of a GPP requires the support of the local government so that it can contribute to regional income.	The authority to formulate policies to support the development of GPP within the regional government and prepare regional income and expenditure budgets from geothermal profit-sharing funds and geothermal production bonuses.	Ensure the implementation of policies and licensing processes in the regions for constructing GPP.
Ministry of State-Owned Enterprises (MSOE)	Increasing renewable energy in the electricity mix is a goal of the general plan for electricity supply at	Fulfilling the installed capacity target for GPP in the PLN Electricity Supply Business Plan.	Encourage PLN to prioritize renewable energy, including GPP.	Increased demand for renewable energy, including GPP, to reduce carbon emissions.	Authority to set targets for additional installed renewable energy capacity in PLN performance indicators.	Ensure the target for adding renewable energy installed capacity is achieved according to the PLN Electricity Supply Business Plan.

Actor	Problem Perception	Objective(s)	Interest(s)	Cause of Problem	Resources	Position
	PLN Electricity Supply Business Plan.					
Ministry of Industry (MI)	Increased need for domestically produced goods and services for developing GPP infrastructure.	Meet domestic component and service levels for GPP infrastructure.	Increasing domestic production capabilities, including design and engineering, that invest and produce in Indonesia for GPP infrastructure.	Encourage investment in the electricity industry in Indonesia to meet the needs for GPP infrastructure using domestically produced goods and services with quality that can operate according to the planned technical life.	Authority to determine the value of domestic component levels of goods and services for GPP.	Increase the level of domestic components with technical specifications by domestic production requirements and quantities to meet GPP infrastructure needs.
Ministry of Investment/ Head of the Investment Coordinating Board (MI/HICB)	Increased investment in renewable energy from GPP to reduce greenhouse gas emissions in the energy sector.	Meeting the need to accelerate and increase capital investment for GPP.	Encourage the implementation of geothermal energy exploitation through the Online Single Submission (OSS) system.	The increasing need for GPP is due to the policy prioritizing purchasing electricity that utilizes renewable energy sources.	Authority for issuing business permits in the form of Indonesian Standard Industrial Classification (ISIC) 06202 Geothermal Permit and Preliminary Survey and Exploration Assignments.	Ensure the implementation of the geothermal energy business through business licensing through ISIC 06202 Geothermal Permit, Preliminary Survey and Exploration Assignments through the OSS system.
	There is an increasing need to utilize space for geothermal environmental services in national park conservation forest areas, grand forest parks, and natural tourism parks to construct GPP.	Fulfilling the need to accelerate and increase capital investment for Suitable Space Utilization Activities (SSUA) for geothermal power generation business activities	Encourage implementation of SSUA for geothermal power generation business activities through the OSS system.	Increased spatial planning requirements for geothermal power generation business activities.	Authority to issue SSUA for the development of a GPP.	Ensure SSUA is implemented for geothermal power generation business activities through the OSS system.
	There is an increasing need to construct GPP using geothermal environmental services	Fulfilling the need to accelerate and increase capital investment for constructing GPP	Encourage the implementation of the utilization of geothermal	The increasing need for GPP is due to the policy prioritizing purchasing electricity	Authority to issue Business Licensing - Geothermal Environmental Services Utilization Permit Exploration	Ensure the use of national park areas, grand forest parks, and natural tourism parks for geothermal

	geothermal electricity after completing exploration activities and having proven geothermal reserves.	and sale agreements so that power plants in the electric power system meet the required system obligation	and having proven geothermal reserves.		of the Commercial Operation Date (COD).	completing exploration activities and having proven geothermal reserves.
SMI	Increasing need for incentives to support the use of GPP.	Support for geothermal development takes the form of financing and funding facilities provided to mitigate risks (de-risking facilities) that hinder the participation of business entities in delivering infrastructure for the geothermal sector.	Carry out assignments for exploration support and financing and exploration financing to increase the involvement of business entities in providing infrastructure for the geothermal industry.	Increasing funding and financing needs by business entities to mitigate risks (de-risking facilities) in providing geothermal infrastructure.	Authority to determine fees and levies, provide funding and infrastructure financing, and provide fiscal facilities in the form of exemption from import duties and no tax for geothermal operations.	Ensure funding support, financing, and fiscal facilities to increase national geothermal production.

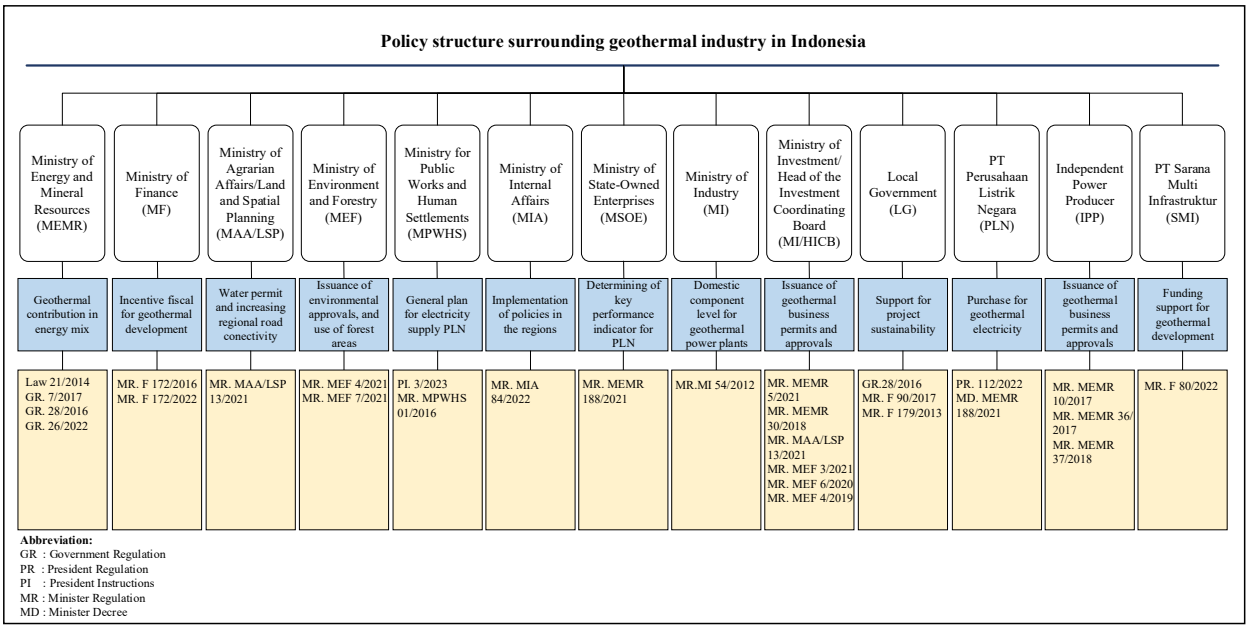

Figure 3: Policy structure surrounding the geothermal industry in Indonesia.

4.2 PESTLE Analysis

Conducting a PESTLE analysis is essential to identify the various stakeholders involved in the geothermal industry. These stakeholders include actors, institutions, and other related parties who have a vested interest in geothermal energy development in Indonesia and may be impacted by the policies and activities of the organizations involved in the industry. By identifying these stakeholders, organizations can better understand their needs and concerns and work to develop strategies that benefit all parties involved.

4.2.1 Politic

The Energy Law plays a crucial role in governing and regulating the energy sector in Indonesia. It provides a legal framework for managing and developing various energy resources in the country, including oil, gas, coal, and renewable energy sources. This law aims to ensure sustainable and efficient use of energy resources, promote energy security, and attract investment in the energy sector. Therefore, the Energy Law is vital for Indonesia's energy industry (Yudha et al., 2018). The Geothermal Law is designed to regulate and supervise geothermal activities conducted for business purposes. Its main objective is to ensure that companies involved in geothermal energy generation adhere to specific guidelines and standards regarding exploration, exploitation, and utilization of geothermal resources. The policy of the geothermal business is shown in Figure 4.

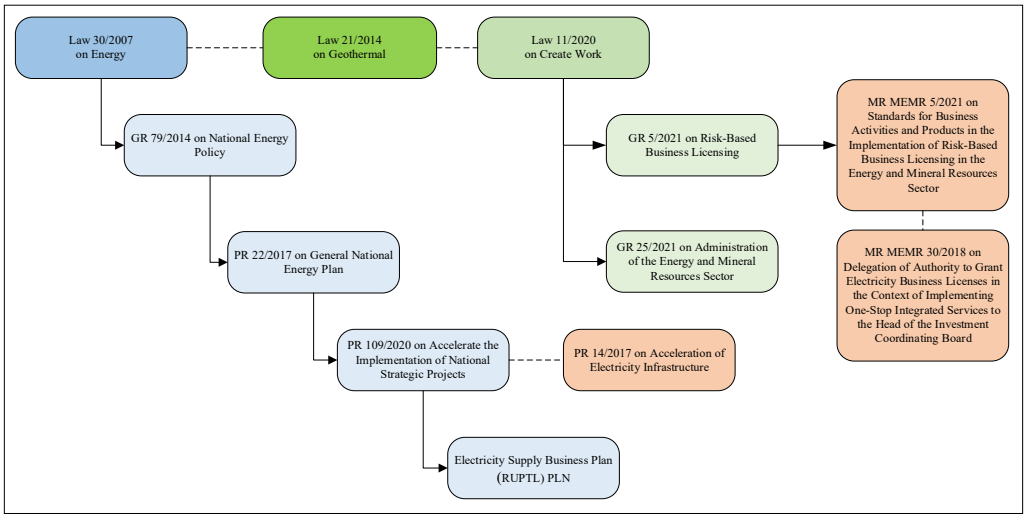

Figure 4: Geothermal business policy.

4.2.2 Economic

To accelerate renewable energy development for electricity supply, the Indonesian Government has set renewable energy price tariffs, including GPP price tariffs with a ceiling price reference. The electricity purchase price policy from GPP has undergone several changes (Setiawan et al., 2022), most recently through Presidential Regulation 112/2022 on the Acceleration of Renewable Energy Development for the Supply of Electric Power. The ceiling price for geothermal electricity is based on location factors (F), as shown in Figure 5.

In the arrangement, the purchase price of electricity from GPP by PLN is determined based on development capacity using the highest benchmark price. The highest benchmark price is the price after being multiplied by a location factor. The purchase price of GPP electricity from IPP by PLN is shown in Tables 2 and 3.

The purchase of electricity from GPP by PLN is determined based on a price matrix, the amount of generation capacity, and the enthalpy value of geothermal exploration results. This pricing matrix can be categorized as a feed-in-tariff (FIT) model based on complex generation capacity and enthalpy variations. Here is an example of a GPP price matrix with a location factor of 1. The price matric of GPP is shown in Tables 4 and 5.

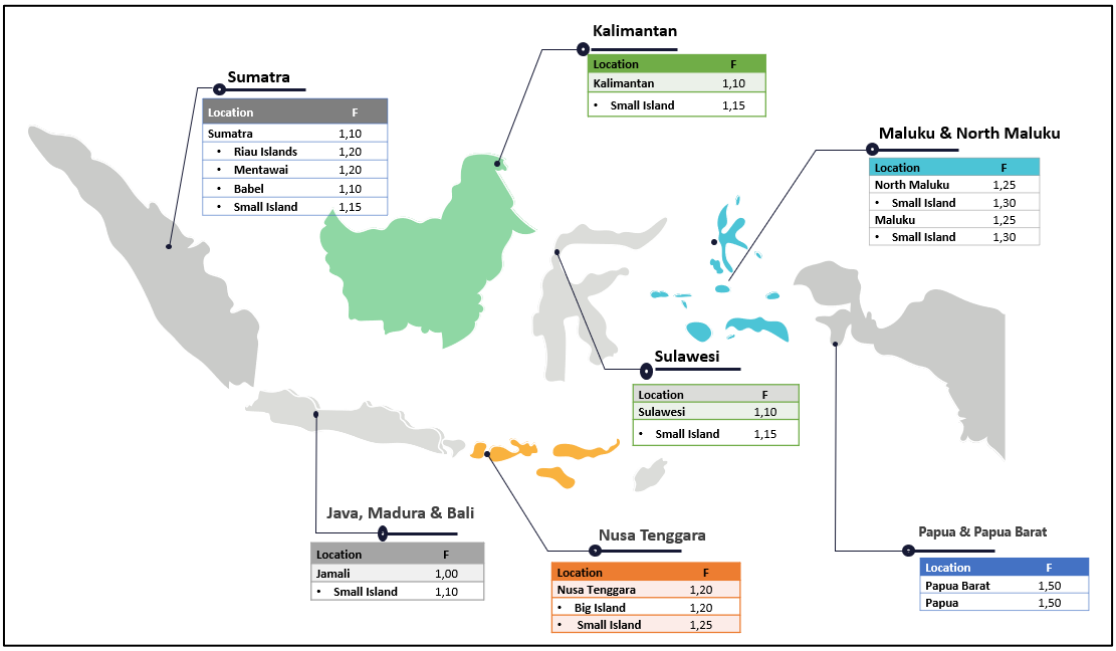

Figure 5: The ceiling price for geothermal electricity is based on location factors.

Table 2: Electric power purchase from the geothermal energy.

Capacity	Ceiling Price Tariff (cent USD/kWh)	
	1st to 10th Year	11st to 30th Year
up to 10 MW	(9.76 x F)*	8.30
>10 MW up to 50 MW	(9.41 x F)*	8.00
>50 MW up to 100 MW	(8.64 x F)*	7.35
>100 MW	(7.65 x F)*	6.50

Table 3: The purchase price of the geothermal steam power equivalent to electricity.

Capacity	Ceiling Price Tariff (cent USD/kWh)	
	1st to 10th Year	11st to 30th Year
up to 10 MW	(6.60 x F)*	5.60
>10 MW up to 50 MW	(6.25 x F)*	5.31
>50 MW up to 100 MW	(5.48 x F)*	4.65
>100 MW	(4.48 x F)*	3.81

Table 4: Price Matrix of GPP Base Price 1.

Base Price 1 (c/kWh)		Development Capacity							
		10	20	30	45	50	55	80	100
Enthalpy (kJ/k	950	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.64
	1,000	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.64

	1,050	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.64
	1,100	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.64
	1,150	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.64
	1,200	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.63
	1,250	9.76	9.41	9.41	9.41	9.41	8.64	8.64	8.43
	1,300	9.76	9.41	9.41	9.41	9.31	8.64	8.64	8.13
	1,350	9.76	9.41	9.41	9.41	9.17	8.64	8.31	7.83
	1,400	9.76	9.41	9.41	9.41	9.32	8.64	8.23	7.74
	1,450	9.76	9.41	9.41	9.31	8.97	8.64	8.13	7.63

Table 5: Price Matrix of GPP Base Price 2.

Base Price 2 (c/kWh)	Development Capacity							
	10	**20**	**30**	**45**	**50**	**55**	**80**	**100**
	8.30	8.00	8.00	8.00	8.00	7.35	7.35	7.35

The following provision applies base price 1 is defined as a base price for years 1 to 10, and base price 2 is defined as a base price for years 11 to 30. Power price (P) can be calculated as base price with the escalation of components fixed operating and maintenance costs (B) and variable operating and maintenance costs (D) maximum of 25%, multiplied by the index which was agreed upon later (United States Principal Party of Interest/USPPI or 2%), added by transmission price (TPC) if applicable.

As can be formulated as follows:

$$P = Pb \times I$$

Pb = Base price that is determined by points 1 and 2 above
I = maximum (1 + 0.25 x Y)
Y = USPPI or 2% according to agreement

4.2.2.1 Financial Obligation from the MF

Financial obligations from the MF include Value Added Tax (PPN), Land and Building Tax (PBB), and Income Tax (PPh). Based on data from four geothermal permit holders who have been operating, the land and building tax rate for land bodies for business entities holding geothermal permits ranges from 0.77% - 1.47%, with an average of 1.36% of revenue. Meanwhile, the land and building tax for onshore land bodies for business entities holding geothermal permits ranges from 0.41% - 1.83%, with an average of 0.52% of revenue. The analysis of taxation for the geothermal development charged by the IPP by the provisions of the statutory regulations is shown in Table 6.

Table 6: The taxation for the geothermal development.

Financial Obligation	Tariff	Regulation
Value Added Tax	11%	Law 7/2021
Land and Building Tax		
Land Bodies	1.36%	MR MF 172/PMK.010/2016
Onshore	0.52%	MR MF 137/PMK.03/2017 The Director General of Taxes Regulation PER-45/PJ/2013
Income Tax	22%	Law 7/2021

4.2.2.2 Financial Obligation from the MEMR

Financial obligations from the MEMR are non-tax state revenues, including geothermal fixed fees and geothermal production fees (royalties). Another financial obligation is the production bonus, which the geothermal holding business entity pays directly to the district/city in the producing area. Costs imposed on IPPs at the geothermal exploitation stage are in the form of fixed exploration and exploitation fees, production fees and production bonuses in the amount of 2 USD/hectare per year for exploration and exploitation fixed fees before COD and 4 USD/hectare for exploration fixed fees and exploitation after COD, a production bonus of 1% on gross income from sales of geothermal steam or 0.5% on gross income from sales of electricity. The financial obligation of the business geothermal energy from the MEMR is shown in Table 7.

Table 7: Financial obligation of the business geothermal energy from the MEMR.

No.	Financial Obligation	Amount of value (USD/IDR)	Explanation	Regulation
1.	Geothermal fixed fees			
	a. Fixed fees of exploration and exploitation before the COD	USD 2/hectare	Per year	GR 26/2022 MR MEMR 5/2023
	b. Fixed fees of exploitation after COD	USD 4/hectare		
2	Geothermal production fees			
	a. Steam	5% x geothermal steam power purchase price	After COD	GR 26/2022 MR MEMR 5/2023
	b. Electricity	2.5% x electric power purchase price		
3.	Production Bonuses			
	a. Steam	0.5% x revenue from steam sales	After COD	GR 28/2016 MR MEMR 23/2017
	b. Electricity	1% x revenue from electricity sales		

4.2.2.3. Financial Obligation from the MEF

Utilization of forest areas for development purposes outside of forestry activities is carried out based on the Forest Area Use Approval (PPKH) and is granted by MEF based on application. Approvals for the use of forest areas in provinces that do not have sufficient forest areas are required to pay PNBP for the use of forest areas, pay compensation for PNBP, and carry out planting in the context of rehabilitating River Watersheds (DAS). Meanwhile, in conservation areas, the non-tax state revenue rate is in the form of fees and levies for Geothermal Environmental Services Utilization Permit. Fees are charged once when the permit is issued, while levies are charged annually. The financial obligation of the business geothermal energy from the MEF is shown in Table 8.

Table 8: Financial obligation of the business geothermal energy from the MEF.

No.	Financial Obligation	Amount of value (IDR)	Explanation	Regulation
1.	Protected Forest and Production Forest Area	Non-tax state revenues: (L1x1xtariff) + (L2x4xtariff)		
	a. Protected Forest	IDR 2,000,000/hectare	Per year	GR 33/2014
	b. Production Forest	IDR 1,600,000/hectare	Per year	
2.	Conservation Area			
	a. Fees for Utilization of Geothermal Environmental Services	IDR 50,000,000/hectare	One time	Revised GR 12/2014
	b. Levies for Utilization of Geothermal Environmental Services	IDR 9,000,000/hectare	Per year	

4.2.3 Social

The socio-cultural aspect is critical in the public acceptance of the project and overcoming social resistance. Understanding citizen's preferences towards the development of geothermal energy leads to a greater understanding of what shapes of strategies and policies should be taken in the project (Ibrohim et al., 2019). When a geothermal project is not managed properly, the social political, and cultural conditions of the community can be a failure factor in geothermal development. Political support was obtained from the regional government and village government (Setiyono et al., 2019). The geothermal business entity has social and environmental responsibilities. This responsibility is an obligation for business entities that carry out business activities in the field of natural resources both inside and outside the business entity environment that are carried out by the Board of Directors based on the company's annual work plan which contains activity plans and budgets needed to implement social and environmental responsibilities. In preparing and determining activity plans and budgets, business entities must pay attention to appropriateness and fairness. Business entities that do not carry out social and environmental responsibilities are subject to sanctions by statutory provisions. Meanwhile, business entities that have played a role and carried out social responsibility can be given awards by the authorized agencies. Social and environmental responsibilities must be implemented by business entities at the exploration stage. Geothermal permit holders are also required to develop development and empowerment programs for local communities around the work area. Local community development and empowerment programs must be implemented by business entities at the exploitation and utilization stages. The social obligation in geothermal development is shown in Figure 6.

4.2.4 Technological

To accelerate the development of electricity infrastructure while still prioritizing the use of domestic products, the MEMR has issued the Ministry Regulation MEMR 11/2024 on the use of domestic products for the development of electricity infrastructure and derivative regulations as shown in Figure 7 and Figure 8. The electricity infrastructure for electricity generation originating from renewable energy sources starts from activities survey to obtain renewable energy sources.

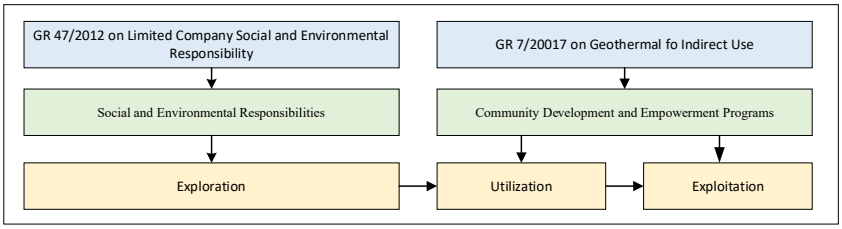

Figure 6: Social obligations in geothermal development.

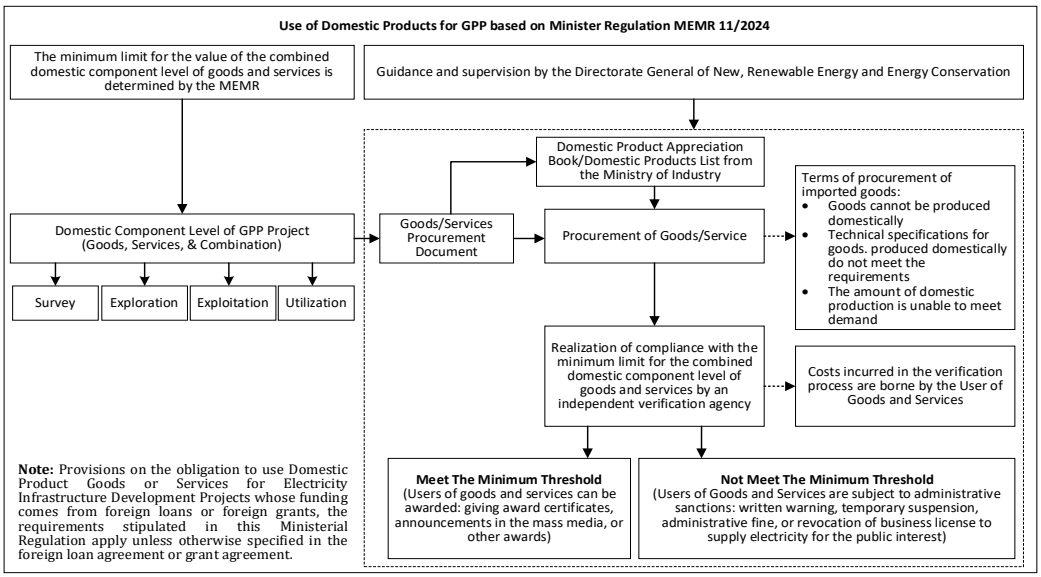

Figure 7: Domestic component level for GPP.

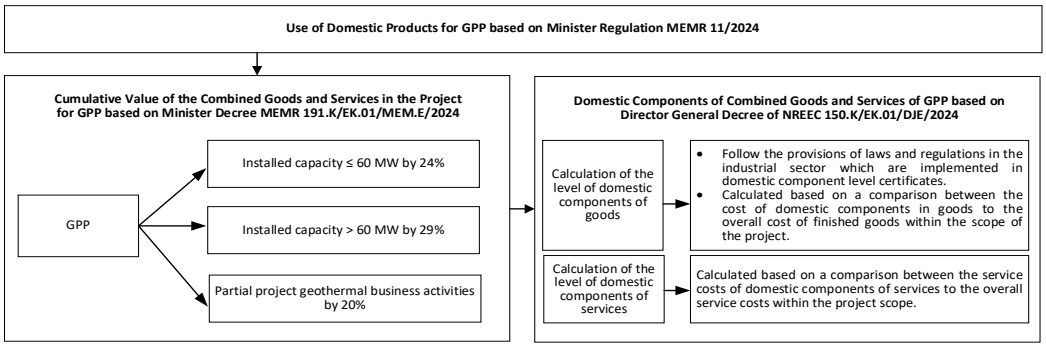

Figure 8: Minimum domestic component level threshold for GPP.

4.2.4 Legal

Geothermal development in Indonesia is regulated by Geothermal Law and its derivative regulations. The utilization of geothermal energy for electricity is the authority of the central government. Meanwhile, direct use of geothermal energy is under the regional government's authority. Regulations in the geothermal sector in Indonesia are the most complete compared to other renewable energy regulations; regulations in the geothermal sector are shown in Figure 9.

4.2.5 Environmental

Environmental Approval documents generally use UKL-UPL at the geothermal exploration stage, but for exploration activities that change the shape of the land and landscape, an AMDAL is required. Meanwhile, at the geothermal exploitation stage, Environmental Approval documents use AMDAL. Based on Ministerial Regulation MEF 4/2021, the types of mandatory activities/businesses that require AMDAL on a scale/scale are infrastructure development with earthworks that have a volume of > 500,000 m3 or a road construction length of > 5 km.

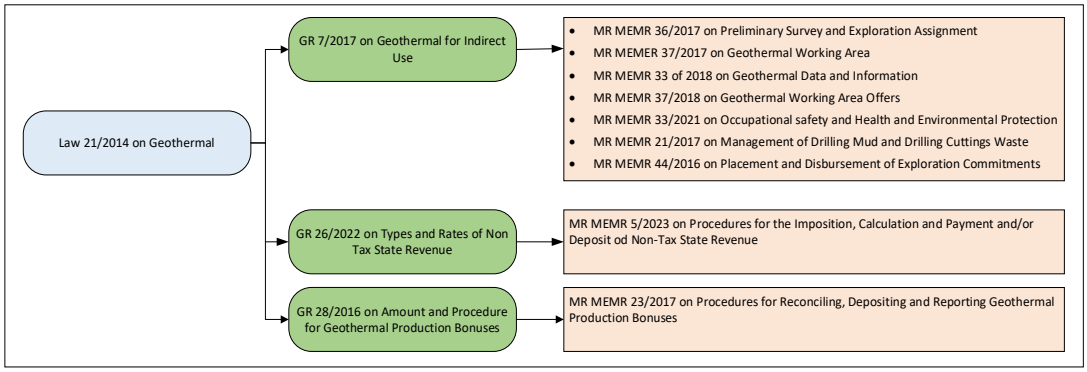

Figure 9: Regulation of geothermal for electricity.

Geothermal activities in protected forest areas or production forests are priority activities outside of forestry activities without being limited by zones/blocks. Meanwhile, for geothermal utilization in conservation forest areas (national parks, grand forest parks, and nature tourism parks). Geothermal environmental services in national parks, grand forest parks, and nature tourism parks mandate that geothermal utilization can be carried out in utilization zones through a conservation area environmental services mechanism. Nazif et al. (2021) studied land status of geothermal resources distribution are 46% private land, 18% conversation forest, 28% protected forest, 4% limited production forest, 3% protected forest, and 1% conservation production forest. The regulation of geothermal utilization in forest areas is shown in Figure 10.

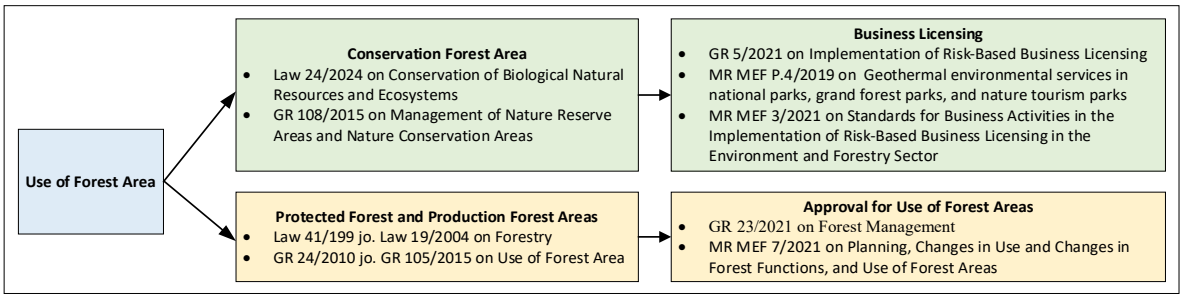

Figure 10: Regulation of geothermal utilization in forest area.

4. DISCUSSION AND RESULT

Based on the multi-actor analysis and PESTLE analysis, there are quite a lot of stakeholders in geothermal development in Indonesia, including Ministries/Agencies, Regional Government, PLN, IPP, SMI, and other stakeholders who need synergy so that obstacles in geothermal development can be overcome. resolved easily. We can see more holistically how certain aspects of PESTLE dynamically impact each other. Although the economic aspect of the geothermal industry is one of the most pressing problems, this aspect can also be considered the starting point for geothermal development in Indonesia.

The regulation of geothermal energy, taking into account political, economic, social, technological, legal, and environmental aspects, is highly comprehensive. It is important to encourage and facilitate the Environmental Approval permits that are currently being processed at the Ministry of Environment and Forestry, including permits in conservation areas. Moreover, providing fiscal and non-fiscal incentives through the Ministry of Finance and imposing state revenue levies from non-taxes by the MEMR can increase the involvement of business entities in developing geothermal energy.

In order to reach the target for geothermal development, MEF can facilitate environmental approval and licensing in conservation forest areas. Additionally, MEF can encourage geothermal development in these areas by changing the function of the Nature Reserve Forest Area into a Nature Conservation Area with utilization zones or blocks. Meanwhile, MF can support geothermal development by providing fiscal and non-fiscal facilities to enhance the economics of geothermal projects. In addition, through PESTLE analysis, we can further highlight the intersecting and overlapping sectoral interests in the geothermal sector. Through PESTLE, a better understanding of the interrelationships of these various aspects is juxtaposed and discussed through stakeholders. In this actor analysis and PESTLE analysis, various stakeholders have been identified who contribute to the development and utilization of geothermal energy, and their relationships are shown in Table 9.

Table 9: Actor Analysis and PESTLE analysis of the geothermal energy industry in Indonesia.

Actors	Political	Economic	Social	Technology	Environment	Legal

IPP		√	√	√	√	√

5. CONCLUSION

The development and utilization of GPP are assessed from the stakeholder aspect using actor analysis to identify and link overlapping and cross-sectoral stakeholder interests in the renewable energy sector in Indonesia. The current policy is still in its initial stages and requires significant improvement, considering that the geothermal industry needs to grow. The need for appropriate policies has made GPP stakeholders and actors face various risks, including economic and technological. The ability of policymakers in Indonesia to identify and mitigate these risks is the key to success in developing geothermal energy.

In the future, it is hoped that the government can formulate breakthrough policies to advance the geothermal sector, such as providing convenience to investors in the geothermal industry and providing fiscal incentives, thereby enabling the management of the geothermal energy supply chain effectively and efficiently. Apart from that, it should be noted that Indonesia's GPP target of 22,000 MW of primary energy mix in 2060 can be achieved. The actor analysis for stakeholders in the geothermal sector will also help strengthen the starting point for formulating a comprehensive national supply chain management framework for geothermal energy.

Keywords: Scholarship impact, Corporate social responsibility, Community empowerment

ABSTRACT

This study evaluates the transformative impact of the Star Energy Geothermal Wayang Windu, Limited (SEGWWL) scholarship program, spanning from 2005 to 2024, on its recipients using the Most Significant Change (MSC) technique. The research reveals that the scholarship has significantly influenced the educational achievements, personal and professional growth, also social contributions of the recipients, many of whom have received support since elementary school. By removing financial barriers and fostering a sense of responsibility and community engagement, the scholarship has enabled recipients to pursue higher education and successful careers. The scholarship has solidified Star Energy's reputation as a catalyst for social change, building unshakable trust and goodwill within the community. Discontinuing this program would risk unraveling these gains, jeopardizing both the social fabric of the community and the company's legacy. The study underscores the imperative to not only maintain but expand this critical initiative, positioning it as a cornerstone of Star Energy's commitment to sustainable and impactful corporate social responsibility.

1. INTRODUCTION

1.1 The Background of the Study

The significance of corporate social responsibility (CSR) has grown substantially in recent years, with companies increasingly recognizing the need to balance economic performance with social and environmental contributions. This is particularly relevant in developing countries, where CSR initiatives can play a vital role in addressing socio-economic challenges. Star Energy Geothermal Wayang Windu, Limited (SEGWWL), a major player in Indonesia's geothermal sector, has integrated CSR into its business model, focusing on community development through education, economic empowerment, social, environment and health. The community development program is based on the results of social mapping carried out by academics. This is an implementation of the collaboration hexahelix concept. The hexa-helix concept is a development of penta-helix concept with addition in the role of law and regulation (Zakaria, 2019).

The SEGWWL scholarship program, initiated in 2005, is a key component of this strategy, aimed at improving educational access and outcomes for underprivileged and high achieving students in the Pangalengan area, thereby fostering sustainable community development (Silvius & Schipper, 2014). This is in line with statistical data that shows that in 2004 the percentage of continuing school from elementary school to junior high school was 16% while in 2019 it increased to 39% as well as the percentage of continuing school from junior high school to senior high school which increased from 39% to 62% (Badan Pusat Statistik, 2004 dan 2020).

Scholarship programs, particularly those funded through CSR initiatives, have been shown to significantly impact students' academic achievements and socio-economic status. Previous studies have demonstrated that financial aid and scholarships not only increase college attendance rates but also enhance academic persistence and completion (Dynarski, 2003; Castleman & Long, 2016). In the context of SEGWWL, the scholarship program targets students across various educational levels, from elementary school to university, with the aim of bridging educational gaps and empowering the community. This study seeks to evaluate the broader impact of this program especially scholarship in university level, focusing on both the personal and social outcomes for the recipients.

1.2 Main Research Problem and General Solution

Despite the well-documented benefits of scholarships, there is a need for more nuanced evaluations that capture the full range of impacts, particularly in the context of CSR-driven programs. Traditional metrics such as graduation rates and academic performance, while important, may not fully reflect the broader social and personal changes brought about by such scholarships. Research indicates that scholarships can influence not only educational outcomes but also long-term career success and community involvement (Erickson et al., 2021; Greene et al., 1997). However, there remains a gap in understanding how these programs impact the recipients beyond the immediate academic environment.

To address this research gap, this study employs the Most Significant Change (MSC) technique, a qualitative evaluation method that collects and analyzes personal stories from scholarship recipients. This technique is particularly effective in capturing the complex and often subjective changes experienced by individuals as a result of educational support. By focusing on the narratives of the scholarship recipients, this study aims to provide a deeper understanding of the personal and social impacts of the SEGWWL scholarship program, offering insights that go beyond traditional quantitative assessments (Dart & Davies, 2003).

2. OBJECTIVE

The objective of this study is to evaluate the impact of the Star Energy Geothermal Wayang Windu, Limited (SEGWWL) scholarship program 2005 to 2024, using the Most Significant Change (MSC) technique to capture both personal and social changes experienced by the recipients. This research is novel in its application of the MSC technique to a CSR-driven scholarship program within the Indonesian context, offering a unique perspective on the role of corporate initiatives in educational and community development. By focusing on the qualitative experiences of scholarship recipients, this study provides a deeper understanding of the program's impact beyond traditional academic metrics.

The scope of this research is centered on analyzing the narratives of scholarship recipients from the Pangalengan area, who have benefited from the SEGWWL program. Data were collected through in-depth interviews with un-structure question, allowing for a comprehensive assessment of the scholarship's impact on personal development, academic success, and community involvement. The findings are expected to contribute to the broader discourse on corporate social responsibility and education, offering valuable insights for both academic researchers and corporate policymakers on the effectiveness of scholarship programs in promoting sustainable development.

3. METHODOLOGY

3.1 The Most Significant Change for Evaluating Program

The Most Significant Change (MSC) technique is widely recognized for its ability to capture qualitative data that reflects the real-life impacts of programs, especially in contexts where outcomes are varied and non-linear. Originally developed for use in international development projects, MSC has since been applied in various fields to evaluate the effectiveness of complex interventions. The technique involves collecting stories from program participants and then analyzing these stories to identify the most significant changes brought about by the program (Dart & Davies, 2003). This approach allows evaluators to understand the diverse ways in which programs influence participants, making it ideal for assessing the impact of the SEGWWL scholarship program.

In evaluating educational interventions, the MSC technique has been praised for its participatory nature, which involves stakeholders in the process of identifying significant changes. This participatory approach ensures that the evaluation reflects the perspectives of those directly affected by the program, thereby providing a more comprehensive understanding of its impact. Research on similar scholarship programs has demonstrated that this method can uncover insights that might be overlooked by more traditional evaluation techniques, particularly regarding the personal and community-level changes that occur as a result of educational support (Mills & Wolf, 2017; Erickson et al., 2021).

The MSC technique's application in this study is further supported by its adaptability to different contexts, making it suitable for analyzing the diverse impacts of the SEGWWL scholarship program across different educational levels and socioeconomic backgrounds. By focusing on the most significant changes, this study aims to provide a rich, nuanced understanding of how the scholarship program has influenced recipients' lives, contributing to both their personal growth and the development of their communities.

3.2 Materials

The materials used in this study primarily consisted of qualitative data collected from scholarship recipients of the SEGWWL program. This data included detailed personal narratives and transcripts from interviews conducted with selected recipients. The study also utilized records and documents related to the SEGWWL scholarship program, such as recipient lists, educational outcomes, and background information on the scholarship administration. The use of the Most Significant Change (MSC) technique required careful selection of respondents who could provide comprehensive and reflective accounts of their experiences, thus serving as the primary source of data (Davies & Dart, n.d.).

3.3 Sample Preparation

The sample preparation involved identifying and selecting scholarship recipients from the Pangalengan area who had received scholarships between 2005-2024. The selection criteria were based on the willingness of recipients to participate and the significance of their achievements as determined by the scholarship's impact on their educational and professional development. Once identified, respondents were contacted and briefed on the study's

purpose, and informed consent was obtained. Data collection was facilitated through structured interviews, which were designed to elicit detailed accounts of the recipients' experiences with the scholarship program, using guidelines established by the MSC technique (Dart & Davies, 2003).

3.4 Experimental Set-up

The experimental setup for this study centered around the application of the MSC technique to evaluate the qualitative impact of the SEGWWL scholarship program. The process involved collecting and analyzing stories from the scholarship recipients, which were then reviewed to identify the most significant changes in their lives attributed to the scholarship. This technique required an iterative approach where respondents' narratives were collected, categorized, and analyzed in multiple stages to ensure comprehensive data interpretation. The structured interviews served as the primary data collection tool, allowing for in-depth exploration of personal and professional changes experienced by the respondents (Davies & Dart, n.d.).

3.5 Specific Literature Review that Led to Research Gaps

A review of existing literature highlights the positive impact of scholarships on students' educational attainment and socio-economic mobility. Studies have consistently shown that scholarships increase college attendance and completion rates, particularly among disadvantaged groups (Gleason & Dynarski, 2002; Bettinger, 2004). Furthermore, research suggests that scholarships can lead to improved academic performance and long-term career success, providing recipients with the financial support and motivation needed to pursue higher education (Dynarski, 2003; Castleman & Long, 2016). However, much of this research has focused on scholarships provided by government and private entities, with relatively little attention given to CSR-driven scholarship programs.

Moreover, while the academic and professional benefits of scholarships are well-documented, there is a lack of studies examining the broader social impacts of such programs, particularly in developing countries. The existing literature does not fully address how scholarships influence recipients' personal development, social integration, and community involvement, aspects that are critical to understanding the full impact of educational support programs (Goldrick-Rab et al., 2009; Deming & Dynarski, 2009). This gap is particularly evident in the context of Indonesia, where the intersection of corporate social responsibility and educational development has not been extensively explored.

This study aims to fill these gaps by applying the MSC technique to evaluate the personal and social impacts of the SEGWWL scholarship program. By focusing on the experiences of scholarship recipients, this research seeks to provide new insights into how CSR-driven scholarships contribute to both individual and community development, thereby expanding the understanding of the role of education in sustainable development.

4. FINDING AND DISCUSSION

4.1 Personal and Professional Growth

The impact of the SEGWWL scholarship program on its recipients has been profound and multifaceted, as evidenced by the narratives of Aji Muharam Somantri, Shandra Ufa Dewi Nugraha, Risye Nuroctaviani Lausi, and Vieska Rofianissa. These individuals have highlighted significant changes in their personal, academic, and professional lives attributable to the scholarship support. Aji Muharam Somantri, who graduated from Bandung State Polytechnic, attributes his current role as a Senior Engineer at Toyota Motor Corporation to the comprehensive support received during his studies, including full tuition coverage and additional financial aid for living expenses. His involvement in various academic and extracurricular activities further facilitated his career development.

Shandra Ufa Dewi Nugraha, a graduate of Padjadjaran University, emphasizes the economic relief and opportunities the scholarship provided, enabling her to continue her education without financial burden. Her active participation in university organizations and committees significantly contributed to her personal growth and the establishment of her current business, Homestay Shavira. Similarly, Risye Nuroctaviani Lausi, who pursued a midwifery degree at Padjadjaran University, experienced enhanced academic focus and professional maturity through the support provided by the scholarship, which included full tuition and accommodation costs. Her role as a Coordinator Midwife at KPBS General Hospital reflects the practical application of her education and the scholarship's impact on her career trajectory.

Vieska Rofianissa, a chemical engineering graduate from Bandung State Polytechnic, underscores the critical financial support received, which allowed her to focus on her studies and eventually secure a position at the National Research and Innovation Agency (BRIN). Her journey illustrates the challenges and successes faced by scholarship recipients, highlighting the significant role of the SEG scholarship in facilitating access to higher education and subsequent professional opportunities.

4.2 Social Impact of Scholarship Program

The social impact of the SEGWWL scholarship program is evident in the way it has influenced not only the recipients' lives but also their families and communities.

The scholarship has empowered recipients to contribute to their communities in meaningful ways. For instance, Aji Muharam Somantri, in addition to his professional achievements, has shared his knowledge with his community by offering advice on electricity efficiency and safety, extending the benefits of his education to others. This form of community involvement indicates that the scholarship program fosters a sense of responsibility and civic engagement among its recipients, encouraging them to give back to their communities.

4.3 Discuss by Comparing and Contrasting from Literature Data

The findings from the SEGWWL scholarship program align with existing research that highlights the transformative impact of financial aid on student outcomes. Studies such as those by Greene et al. (1997) and Mills & Wolf (2017) demonstrate that scholarships significantly improve students' academic achievements and increase college attendance and completion rates. The scholarship recipients in this study experienced similar benefits, using the financial support to access higher education and achieve notable professional successes. The SEGWWL scholarship's non-binding nature, which allows recipients the freedom to choose their career paths post-graduation, further enhances its positive impact by supporting individual autonomy and career development.

However, the SEGWWL program's broader social implications, such as recipients financing their siblings' education, suggest a ripple effect that is less commonly discussed in the literature. This aspect of the scholarship's impact, where the benefits extend to the recipients' families and communities, echoes findings by Erickson et al. (2021), who noted similar patterns in the Louisiana Scholarship Program. This broader impact highlights the potential of scholarships to contribute to community development and social mobility, beyond the immediate academic achievements of the recipients.

4.4 Discuss the Importance of the Findings and Their Scientific and Practical Implications

The findings from this study underscore the importance of CSR-driven scholarship programs like the SEGWWL scholarship in fostering educational attainment and socio-economic mobility. By providing financial support, these programs remove significant barriers to higher education for underprivileged and high achieving students, enabling them to achieve their academic and professional potential. The transformative personal development reported by the recipients, such as the shift in character and enhanced self-confidence, is a testament to the scholarship's role in not only supporting education but also in shaping resilient, responsible, and ambitious individuals.

Scientifically, this study contributes to the understanding of the broader social impacts of scholarship programs, particularly in developing countries. It demonstrates that the benefits of scholarships extend beyond the individual recipients to their families and communities, suggesting a potential for long-term socio-economic development. Practically, the insights gained from this study can inform the design and implementation of future scholarship programs, emphasizing the need for comprehensive support that includes not only financial aid but also opportunities for personal and professional development. The study’s findings support the expansion of such programs to reach more students and suggest that involving multiple stakeholders in the process can enhance the overall impact of these educational initiatives.

4.5 Highlight Findings

1. **Scholarship Recipients had been Awarded the Scholarship since Elementary School**
   Among the interviewees, it was found that 3 out of 4 scholarship recipients had been awarded the scholarship since elementary school as a recognition of their academic achievements. This early support has significantly motivated these students to maintain and improve their academic performance. Beyond benefiting the recipients, this initiative has also generated a positive impact for the company in the form of goodwill, as Star Energy has become a well-known and trusted name within the community. The company’s contribution is directly felt by the public, enhancing trust in Star Energy, particularly when families consider higher education opportunities for their children supported by these scholarships.

2. **Increase Social Mobility with More Confidence**
   This scholarship also plays an important role in increasing social mobility for its recipients. By providing the financial resources necessary to access higher education, scholarship programs for outstanding students from various levels of education, the program has enabled recipients from economically disadvantaged backgrounds to gain more confidence for continue a higher education and secure professional roles that would otherwise have been inaccessible. This upward social mobility is a testament to the scholarship’s role in reducing socio-economic disparities and promoting equality of opportunity within the community.

3. **Breaking the Cycle of Educational Disadvantage**
   The scholarship has had a significant impact on breaking the cycle of low educational attainment in the Pangalengan area. Many recipients, like Shandra Ufa Dewi Nugraha and Vieska Rofianissa, are now supporting their siblings' education, effectively using their own educational advancement to elevate the educational status of their families. This cascading effect illustrates how the scholarship program not only benefits individual recipients but also extends its impact to future generations, contributing to a gradual upliftment of the community's educational level.

5. CONCLUSION

This study highlights the significant impact of the Star Energy Geothermal Wayang Windu (SEGWWL) scholarship program on its recipients, both in terms of personal development and broader social influence. The scholarship has been instrumental in providing educational opportunities to underprivileged and high achieving students, enabling them to achieve academic success and professional growth.

The Star Energy Geothermal Wayang Windu (SEGWWL) scholarship program has proven to be a transformative force, not only in the lives of its recipients but also in the reputation and social responsibility of the company. To maximize its impact, the SEGWWL scholarship program should consider expanding its reach to include more students, particularly at the undergraduate level, and partnering with additional universities. By investing in the education of underprivileged and high achieving students, the program has unlocked pathways to higher education, professional success, and personal growth that would otherwise remain inaccessible. The Most Significant Change (MSC) technique has revealed that this scholarship is more than financial aid—it is a catalyst for change, fostering resilience, leadership, and a commitment to giving back to the community. The positive ripple effects of this program extend beyond the individual recipients, enhancing the educational standards of entire families and strengthening the social fabric of the community. For Star Energy, the program is not just a philanthropic endeavor but a strategic investment in building long-term goodwill and trust within the community. To dismantle or diminish this program would be to undermine a vital bridge between corporate responsibility and community development, risking both the company's reputation and its connection with the people it serves. Therefore, maintaining and expanding this scholarship program is not just advisable—it is essential for sustaining the positive legacy that Star Energy has built.

Keywords: geothermal, derivative product, secondary product

ABSTRACT

Globally, the development of geothermal projects is not only for electricity generation, but also for its other value chain and derivative product for increasing revenue beyond ceiling tariff. This research explores the expansive realm of geothermal energy derivative products, drawing vital insights from the United States to propose strategic implementations for Indonesia. The research commences with an in-depth examination of the U.S. geothermal business model, emphasizing electricity generation and the integral role of the electricity grid. It addresses the market's challenges and opportunities, focusing on how geothermal derivative products are interwoven into U.S. business strategies.

The paper delineates various geothermal value chain and derivative products prevalent in the U.S., including direct use, and groundbreaking methods for extracting lithium, silica, and hydrogen. Each product is scrutinized for its economic viability, market potential, environmental benefits, and the existing policy framework that supports its development. This examination unveils the multifaceted value these derivatives add to the traditional geothermal energy spectrum, highlighting their potential to enhance energy sustainability and economic growth. Looking forward, the study delves into the future landscape of geothermal derivatives in the U.S., spotlighting research initiatives, innovative technologies, and pilot projects that promise to redefine geothermal energy utilization. This forward-looking perspective not only signifies growth in the U.S. but also sets a benchmark for Indonesia.

The core of the research encapsulates a comparative analysis, extracting lessons from the U.S. to envisage a tailored geothermal derivative implementation strategy for Indonesia. By dissecting successful U.S. practices, the study identifies transferable strategies, policy recommendations, and technical prerequisites tailored to Indonesia's geothermal context. It underscores the necessity for a supportive policy environment, strategic investment, and technological adaptation to foster a robust geothermal derivative market in Indonesia.

In its culmination, the paper synthesizes key insights, offering a strategic roadmap for Indonesia to harness the untapped potential of geothermal derivatives. By integrating lessons from the U.S., it advocates for a holistic approach that aligns economic, environmental, and technological objectives, thereby propelling Indonesia towards a sustainable energy future and positioning it as a frontrunner in geothermal energy innovation. This research stands as a pivotal reference for stakeholders in the geothermal energy sector, policy-makers, and the academic community, providing a comprehensive framework to guide the strategic expansion of geothermal derivative products in Indonesia and beyond.

1. INTRODUCTION

The utilization of geothermal energy has predominantly centered around electricity generation, yet the potential of geothermal resources extends far beyond this conventional application. Globally, there is a growing interest in exploring geothermal derivative products as a means to enhance revenue streams and promote sustainable energy practices. This study delves into the diverse realm of geothermal energy derivative products, drawing pivotal insights from the United States, a leader in geothermal innovation, to propose strategic implementations for Indonesia. By examining the U.S. geothermal business model, this research aims to identify transferable strategies that can bolster Indonesia's geothermal industry, thereby fostering economic growth, energy sustainability, and environmental benefits.

1.1 Research Background

In the quest for sustainable energy solutions, geothermal energy emerges as a pivotal player within the renewable energy landscape. With its ability to provide baseload power and minimal environmental footprint, geothermal energy stands out as a particularly resilient and reliable source. This paper explores the expanded role of

geothermal energy beyond conventional electricity generation, delving into its derivative products as innovative revenue streams.

Geothermal energy, a renewable and sustainable resource, has long been harnessed for electricity generation. However, as the global energy landscape evolves, there is an increasing emphasis on maximizing the value of geothermal resources by leveraging derivative products. These secondary products, such as district heating and cooling systems, and the extraction of valuable minerals like lithium, silica, and hydrogen, present significant opportunities for enhancing the economic viability and sustainability of geothermal projects.

The United States has been a pioneer in geothermal electricity generation, leveraging its rich geothermal resources to produce reliable, renewable energy which currently become 1st rank of top geothermal producer country by installed capacity (see Figure 1) (Thinkgeoenergy, 2024; Al Asy'ari, Adityatama, Brilian, Erichatama, & Purba, 2024; Richter, 2023). As the largest producer of geothermal power, the U.S. harnesses the earth's heat, primarily concentrated in the western states such as California and Nevada, to generate electricity. This process involves using steam produced from natural geothermal reservoirs to power turbines. The technology has evolved over decades, with the U.S. continuously expanding its capacity through both traditional hydrothermal plants and innovative approaches like Enhanced Geothermal Systems (EGS).

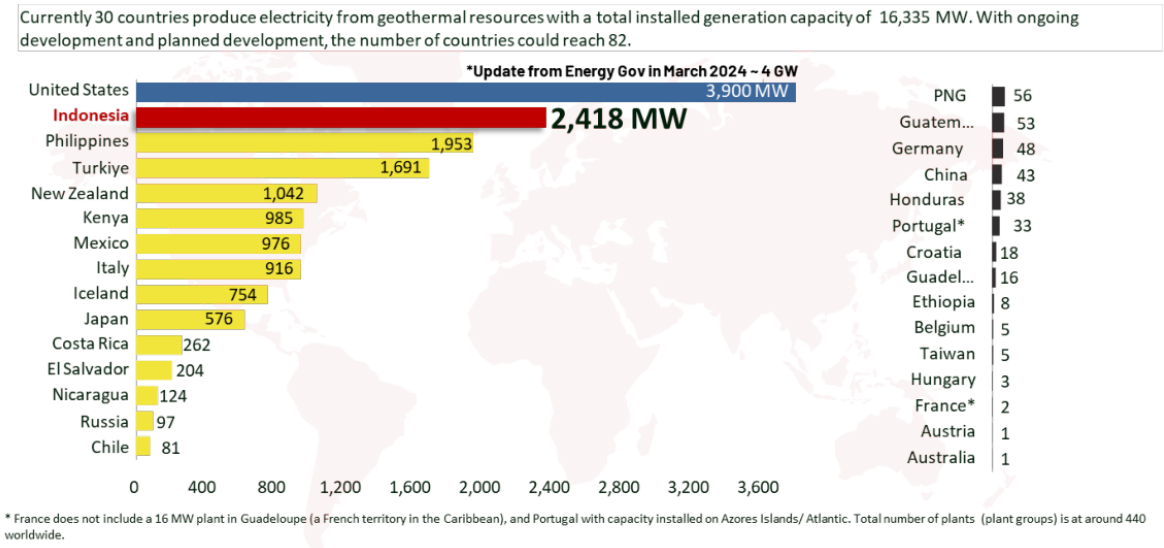

Figure 1: Global update of geothermal power plant installed capacity as per update January 2024. Modified from (Thinkgeoenergy, 2024; Al Asy'ari, Adityatama, Brilian, Erichatama, & Purba, 2024; Richter, 2023)

In the United States, the integration of geothermal derivative products into business models has been instrumental in overcoming market challenges and capitalizing on new opportunities. The U.S. experience provides a rich repository of knowledge on the economic, environmental, and policy dimensions of geothermal derivatives. By drawing lessons from the U.S., this study aims to inform the development of a robust geothermal derivative market in Indonesia, a country with vast untapped geothermal potential.

1.2 Research Objectives and Method

The primary objective of this research is to explore and evaluate the potential of geothermal derivative products in the United States and propose strategic implementations for Indonesia. This objective is pursued through a comprehensive examination of the U.S. geothermal business model, focusing on electricity generation and the integral role of the electricity grid. The study seeks to address the following specific objectives:

1. *Identify and analyze geothermal value chain and derivative products prevalent in the United States*, including district heating and cooling systems, and methods for extracting lithium, silica, and hydrogen. This analysis will cover the economic viability, market potential, environmental benefits, and policy frameworks that support these products.
2. *Assess the future landscape of geothermal value chain and derivatives in the U.S*, highlighting ongoing research initiatives, innovative technologies, and pilot projects. This forward-looking analysis will provide insights into potential growth areas and technological advancements in the geothermal sector.
3. *Conduct a comparative analysis to extract lessons from the U.S. experience*, develop a tailored geothermal value chain and derivative product implementation strategy for Indonesia. This will involve

identifying transferable strategies, policy recommendations, and technical prerequisites suited to Indonesia's geothermal context.

4. *Develop Key Insights for Indonesia*, synthesizing key insights from the U.S. and advocating for a holistic approach that aligns economic, environmental, and technological objectives to foster a sustainable geothermal energy future in Indonesia.

To achieve these objectives, the research adopts a multi-method approach, encompassing a holistic review of existing literature on geothermal energy and derivative products, with a focus on U.S. practices and experiences. Then, Detailed case studies of successful geothermal derivative projects in the United States, providing practical insights and lessons learned. This study also conducts a systematic comparison of the geothermal sectors in the U.S. and Indonesia, identifying similarities, differences, and areas for potential adaptation. Moreover, the authors engage with key stakeholders in the geothermal industry, including policymakers, industry experts, and academic researchers, to gather qualitative insights and validate findings.

By integrating these methods, the research aims to provide a comprehensive framework for leveraging geothermal derivative products in Indonesia, thereby contributing to the country's energy diversification and sustainability goals.

2. OVERVIEW OF GEOTHERMAL ELECTRICITY GENERATION IN THE UNITED STATES

The United States holds the prestigious position of being the leading producer of geothermal electricity globally, largely attributed to its extensive and well-managed geothermal resources concentrated in the western states such as California and Nevada. The foundation of geothermal energy utilization in the U.S. is built upon decades of technological advancements and strategic policy frameworks that have cultivated a robust infrastructure capable of leveraging the earth's heat effectively. This heat is primarily harnessed through hydrothermal power systems, where naturally occurring steam and hot water from the earth's crust drive turbines to generate electricity.

Geothermal power plants in the U.S. have evolved through three main technological stages: dry steam, flash steam, and binary cycle. Each technology corresponds to the specific characteristics of geothermal reservoirs, optimizing energy extraction based on steam quality and temperature. For instance, the Geysers in California, the largest geothermal complex globally, utilizes dry steam directly emitted from the earth to power turbines, showcasing one of the oldest and most efficient forms of geothermal electricity generation.

The integration of Enhanced Geothermal Systems (EGS) marks a significant technological shift, aimed at expanding geothermal applications beyond natural hydrothermal resources. EGS involves artificially creating reservoirs in hot dry rock formations, which are abundant but previously inaccessible for energy production. This innovation not only broadens the geographical scope of geothermal energy production but also enhances its reliability and output, ensuring a consistent energy supply regardless of natural hydrothermal availability. The economic viability of these systems has seen continuous improvement, supported by both governmental incentives and private investments. Initiatives such as the Geothermal Technologies Office (GTO) under the U.S. Department of Energy focus on advancing technologies that reduce costs and risks associated with geothermal development. Such policies not only reinforce the operational capacities of geothermal facilities but also stimulate research and development in next-generation geothermal technologies.

By meticulously harnessing these advanced technologies and supportive policies, the U.S. continues to enhance its geothermal electricity generation capacity, setting a formidable benchmark in both technological innovation and sustainable energy practices. This comprehensive approach underpins the U.S. geothermal sector’s success, providing valuable lessons and adaptable strategies for countries like Indonesia, aiming to escalate their geothermal development to a similar echelon of energy efficiency and economic profitability.

Figure 2 presents a detailed overview of the organizational and regulatory framework of the U.S. electricity market. The map segment delineates the various electricity regions managed by independent system operators (ISOs) and regional transmission organizations (RTOs), which are instrumental in coordinating, controlling, and monitoring the electrical grid as well as facilitating electricity market operations. These entities play a critical role in ensuring the reliability of electricity supply and the integration of diverse power sources, including renewable energies like geothermal, into the grid. The figure also encapsulates the three-tier regulatory structure that governs the U.S. electricity market, consisting of federal, state, and municipal levels. At the federal level, entities like the Department of Energy (DOE) and the Federal Energy Regulatory Commission (FERC) set broad policies and regulations that ensure an open and non-discriminatory transmission grid, promoting competition and enhancing the economic efficiency of the electricity market. State regulators, such as the Public Utilities Commission of Nevada, tailor these policies to local contexts, addressing state-specific energy needs and conditions. At the municipal level, agencies manage local energy services and regulatory compliance, ensuring that the federal and state policies are effectively implemented in urban and rural communities alike.

This comprehensive structure supports a stable, reliable, and adaptable energy system, crucial for integrating sustainable energy practices. Such a framework is particularly relevant when considering the expansion of geothermal energy usage in the United States, as it highlights the critical role of regulatory bodies and market operators in facilitating the growth of renewable energy within an established grid infrastructure. The figure underscores the necessity for robust governance and coordinated management in fostering a sustainable and efficient energy market, serving as a model for other countries aiming to enhance their energy systems.

Transitioning from a general overview of the electricity models and regulatory frameworks in the United States, it is essential to examine how demographic factors, specifically population density, influence the structuring and efficiency of these models. Figure 3 delves into the relationship between population density and the U.S. electricity market, highlighting the disparity in retail competition across various states.

Figure 3 illustrates the significant impact of population density on the electricity market model in the United States, categorizing states into those with dense and sparse populations. The map color-codes states according to their level of retail electricity competition—full, partial, or none—which correlates strongly with population density. States with high population densities, such as those in the Northeast and parts of the West Coast, are marked in green, indicating full retail competition. This competition is viable due to high electricity demand and the economic efficiency of shorter distribution networks in these areas, making them attractive for energy providers.

Conversely, states with low population densities, primarily located in the Midwest and parts of the Rocky Mountain region, are depicted with striped patterns. These areas have partial or no retail competition, attributed to lower electricity demand and the logistical challenges posed by longer distribution lines required to connect dispersed consumers. The pie charts adjacent to the map further quantify this distribution, showing that only a small fraction of states have fully embraced retail competition, with the majority having partial or none, reflecting the logistical and economic constraints in less populated areas.

This visualization underscores the complexities and regional variations in the U.S. electricity market, influenced by demographic factors. The analysis reveals that while densely populated areas can support a competitive market due to their infrastructure and demand, sparsely populated areas face inherent challenges that deter competitive retail electricity markets. Understanding these dynamics is crucial for policymakers and market designers aiming to enhance energy efficiency and market competitiveness across diverse geographic and demographic landscapes.

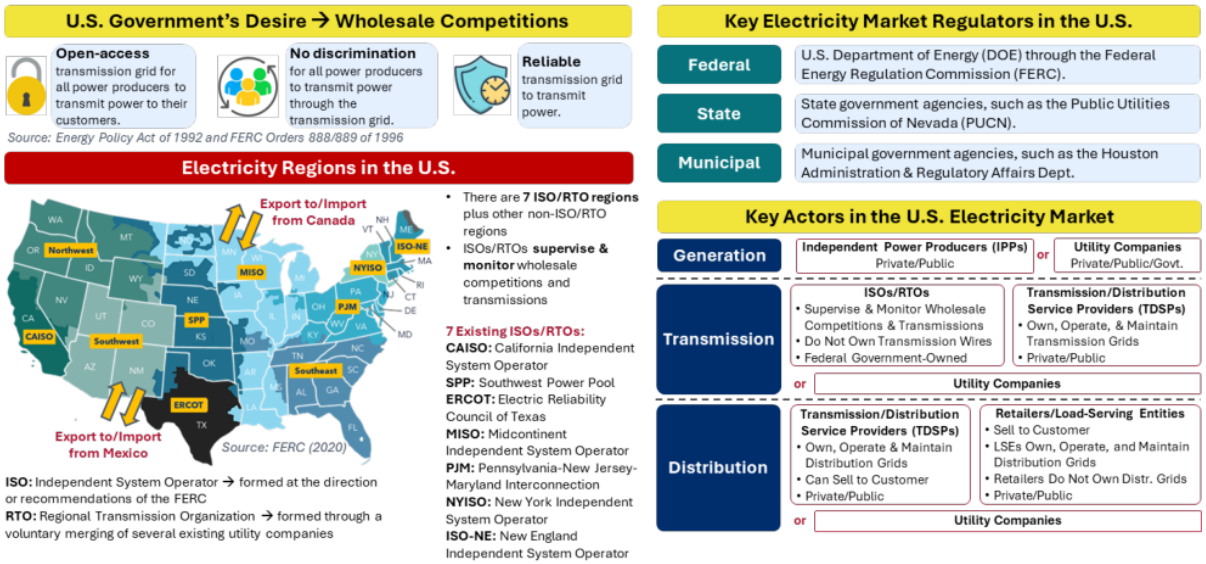

Figure 2: United States Electricity Model Highlight Modified from (Geoenergis, 2024a).

Building on the discussion of how population density influences the structure of electricity markets, it is essential to delve deeper into the various models of electricity market structures that are employed across the United States. These models reflect different approaches to regulation, competition, and service provision, shaped by historical, economic, and demographic factors. Figure 4 presents an overview of four distinct electricity market models operating within the United States, each characterized by different levels of integration and competition.

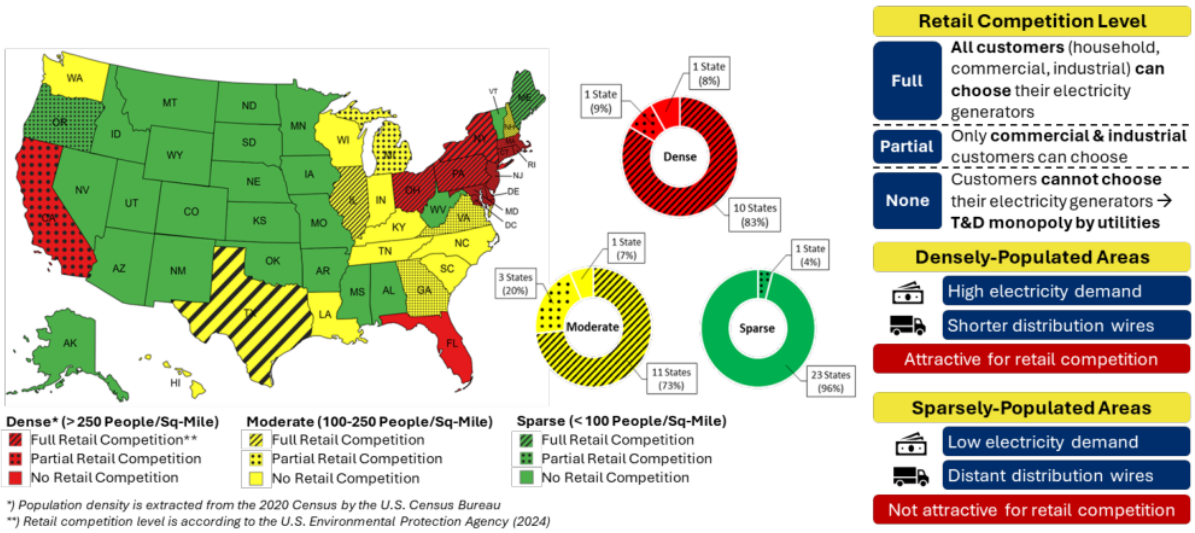

Figure 3: Influence of Population Density to the U.S. Electricity Market Model Modified from (Geoenergis, 2024a).

Model 1: Vertically Integrated In the traditional vertically integrated model, a single monopoly utility is responsible for all stages of electricity production, from generation to transmission and distribution, ending with customer billing. This model is prevalent in areas where a single utility company controls the entire process, often regulated by state agencies to ensure service provision and price control. This setup is common among state-owned utilities and investor-owned utilities (IOUs), which manage extensive infrastructure and serve a large customer base. Despite the potential for conflicts of interest between utility owners and customers, this model benefits from streamlined operations and centralized control.

Model 2: Vertically Integrated with a Single Buyer The single buyer model introduces a limited level of competition by allowing independent power producers (IPPs) to sell electricity to a centralized purchasing agency, which then manages transmission and distribution to end consumers. This model is typically found in restructured markets where the vertically integrated utility remains, often state-owned, and aims to introduce competition at the generation level while maintaining a monopoly over transmission and distribution. This approach seeks to leverage competitive pricing from IPPs while ensuring stable and regulated delivery to consumers.

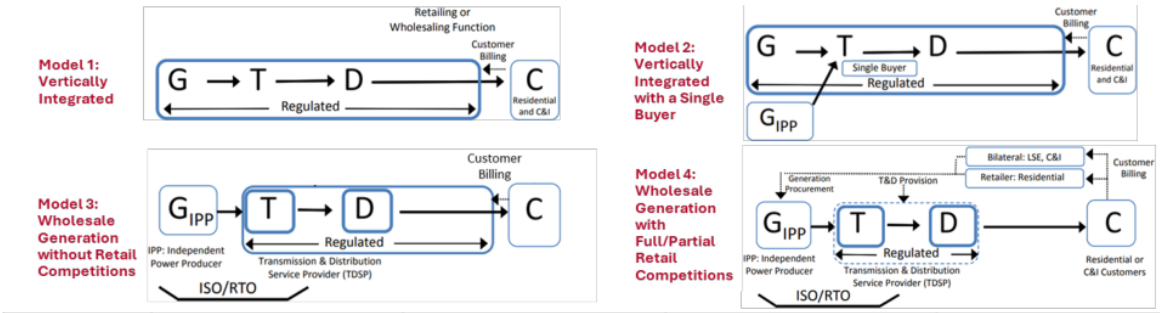
Model 3: Wholesale Competition without Retail Competition The wholesale competition model allows for greater market dynamics by enabling multiple generators to sell electricity directly to distribution companies (Discos) or load-serving entities (LSEs) through an open transmission network managed by an independent system operator (ISO) or regional transmission organization (RTO). While Discos or LSEs may still hold monopolies over local distribution, the open access to transmission lines encourages competitive pricing and efficient generator dispatch. This model is common in several restructured markets globally, including parts of the U.S., the UK, and Australia.

Model 4: Wholesale Competition with Full/Partial Retail Competition In the most competitive model, both wholesale and retail electricity markets are open to competition. Customers have the freedom to choose their electricity suppliers from a variety of retail providers, who purchase electricity from competing generators through an open transmission network. This model supports a fully competitive environment, fostering innovation and customer-centric services. Regulatory oversight ensures that transmission and distribution remain reliable and fair, often through separate entities such as Transmission Service Providers (TSPs) and Distribution Service Providers (DSPs). The Electric Reliability Council of Texas (ERCOT) is a prominent example, offering extensive retail choice and competitive market dynamics.

Each of these models represents different strategies for managing the balance between regulation and competition, reflecting the unique needs and circumstances of various regions. Understanding these models is crucial for designing effective policies and frameworks that can enhance the efficiency, reliability, and sustainability of electricity markets.

Having explored the general electricity market models and their regulatory frameworks, it is pertinent to examine specific examples of how these models are implemented across various states in the U.S., particularly those with significant geothermal resources. Figure 5 focuses on prominent electricity market models in key geothermal states, highlighting how different regulatory and market structures support the integration and utilization of geothermal energy within these states.

Each state's approach to integrating geothermal energy within its electricity market model demonstrates the diverse strategies employed across the U.S. These models reflect the varying degrees of market competition and regulatory oversight, tailored to each state's specific needs and resources. Understanding these different implementations provides valuable insights into how geothermal energy can be effectively managed and expanded within various regulatory frameworks.



Parameter	Model 1	Model 2	Model 3	Model 4
Generation actor	Utility companies (private/public/government)	• Utility companies (private/public/government) • IPPs (private/public)	IPPs (private/public)	IPPs (private/public)
Transmission actor	Utility companies (private/public/government)	Utility companies (private/public/government)	• ISOs/RTOs (federal government) • TDSP (private/public)	ISOs/RTOs (federal government)
Distribution actor	Utility companies (private/public/government)	Utility companies (private/public/government)	• TDSP (private/public) • LSEs (private/public)	• Retailers (private/public) • LSEs (private/public)
Generation pricing mechanism	None (due to vertical monopoly by utility companies)	Fixed price → future market	• Wholesale price → spot market (minute-basis) • Fixed price → future market	• Wholesale price → spot market (minute-basis) • Fixed price → future market
Customer pricing mechanism	Fixed price (daily/monthly/ seasonal) → future market	Fixed price (daily/monthly/ seasonal) → future market	Fixed price (daily/monthly/ seasonal) → future market	Fixed price (daily/monthly/ seasonal) → future market
Customer billing	To utility companies	To utility companies	To TDSPs	• Residential → to retailers • C&I → to LSEs

Figure 5: Prominent Electricity Market Model in the U.S. "Geothermal States" Modified from (Geoenergis, 2024a).

3. CURRENT UNITED STATES PLAN FOR INCREASING GEOTHERMAL EXPOSURE TOWARDS NET ZERO FUTURE

As the global community intensifies its efforts to combat climate change, the United States has embarked on an ambitious journey to achieve a net-zero carbon future by mid-century. Central to this initiative is the strategic expansion of geothermal energy, a versatile and sustainable resource with the potential to provide continuous, reliable power while significantly reducing greenhouse gas emissions. This section explores the current plans and strategies employed by the U.S. to enhance geothermal energy utilization, examining the roles of technological innovation, policy support, and market incentives in driving this transition.

The United States' plan to increase geothermal exposure as part of its strategy to achieve a net-zero carbon future is multifaceted, involving advancements in technology, supportive policy frameworks, and targeted market incentives. One of the key components of this plan is the development and deployment of Enhanced Geothermal Systems (EGS). EGS technology allows for the extraction of geothermal energy from dry, non-porous rocks by artificially creating reservoirs through hydraulic stimulation. This innovation significantly expands the geographic and geological scope of geothermal energy production, making it viable in regions previously considered unsuitable for traditional hydrothermal plants.

Federal initiatives, such as those spearheaded by the U.S. Department of Energy (DOE), play a crucial role in advancing geothermal technologies. The DOE's Geothermal Technologies Office (GTO) focuses on research, development, and demonstration projects aimed at reducing the costs and risks associated with geothermal energy deployment. Programs like the Frontier Observatory for Research in Geothermal Energy (FORGE) are at the forefront of testing and validating EGS technologies, providing a blueprint for future large-scale implementations. Also, various geothermal value chain and derivative product is increasing the exposure of geothermal energy in the United States.

In addition to technological advancements, policy support is pivotal in fostering an environment conducive to geothermal energy growth. The extension of federal tax credits, such as the Investment Tax Credit (ITC) and Production Tax Credit (PTC), provides significant financial incentives for geothermal projects. These credits lower the capital costs for developers, making geothermal projects more economically attractive. Furthermore, state-level policies and renewable portfolio standards (RPS) mandate utilities to include a certain percentage of renewable energy in their supply mix, further driving the demand for geothermal power.

Market incentives also play a vital role in promoting geothermal energy. The establishment of competitive power purchase agreements (PPAs) ensures stable revenue streams for geothermal developers, encouraging investment in new projects. Additionally, the integration of geothermal energy into state and regional grid systems enhances grid reliability and resilience, supporting broader energy market stability.

The U.S. geothermal strategy also includes efforts to streamline regulatory processes and reduce permitting times, addressing one of the significant barriers to geothermal development. Collaborative initiatives between federal and state agencies aim to harmonize regulations and simplify the approval process for geothermal projects, thus accelerating their deployment.

By leveraging these technological, policy, and market mechanisms, the United States aims to significantly expand its geothermal energy capacity, contributing to its overarching goal of a net-zero carbon future. This strategic approach not only supports the transition to a sustainable energy system but also positions geothermal energy as a cornerstone of the U.S. renewable energy portfolio.

To understand the current landscape and future potential of geothermal energy in the United States, it is crucial to examine the historical trends in geothermal capacity expansion. This historical perspective provides insights into the growth patterns, technological advancements, and regional developments that have shaped the U.S. geothermal industry. Figure 6 illustrates the installed geothermal capacity in the U.S. from 1960 to 2023, highlighting contributions from major geothermal fields and key periods of deployment.

Figure 6 provides a comprehensive overview of the historical installed geothermal capacity in the United States, segmented by field location and spanning from 1960 to 2023. The graph delineates significant growth phases and the contribution of various geothermal fields to the overall capacity.

From 1960 to 1990, the U.S. geothermal industry experienced a rapid deployment rate of 81.3 MW per year, primarily driven by the development of major fields such as The Geysers in California. The Geysers, the largest geothermal field in the world, played a pivotal role during this period, significantly boosting the national capacity. This early growth phase was characterized by pioneering

technological advancements and substantial investments in geothermal infrastructure. Post-1990, the deployment rate slowed to 35.7 MW per year, reflecting a period of consolidation and strategic expansion. The development of additional fields such as Salton Sea, Coso, McGinness Hills, and Heber contributed to this growth. Notably, these top five fields collectively account for 70% of the total installed capacity as of 2023, underscoring their critical importance to the U.S. geothermal landscape.

The graph also highlights the cumulative contributions of these fields:

- **The Geysers**: With a total capacity of 1,634 MW, it constitutes 43% of the national total, illustrating its dominance in the sector.
- **Salton Sea**: Contributing 448 MW (12%), this field has been instrumental in maintaining steady capacity growth.

- **Coso**: With a capacity of 270 MW (7%), it has been a significant player in the geothermal market.
- **McGinness Hills**: Adding 174 MW (5%) to the total capacity, this field represents the continued expansion into Nevada's geothermal resources.
- **Heber**: With a contribution of 162 MW (4%), it underscores the role of diversified geographic development.

The right side of the figure provides a summary of the capacity contributions and average deployment rates. Out of the 37 geothermal fields, the top five fields contribute 41% of the total capacity, highlighting their strategic importance. The average deployment rate reflects the periods of rapid initial growth and subsequent steady expansion.

By analyzing these historical trends, we gain valuable insights into the factors that have driven geothermal development in the U.S., including technological innovation, resource availability, and policy support. This historical context is crucial for shaping future strategies to enhance geothermal energy deployment, aiming towards the ambitious goal of a net-zero carbon future.

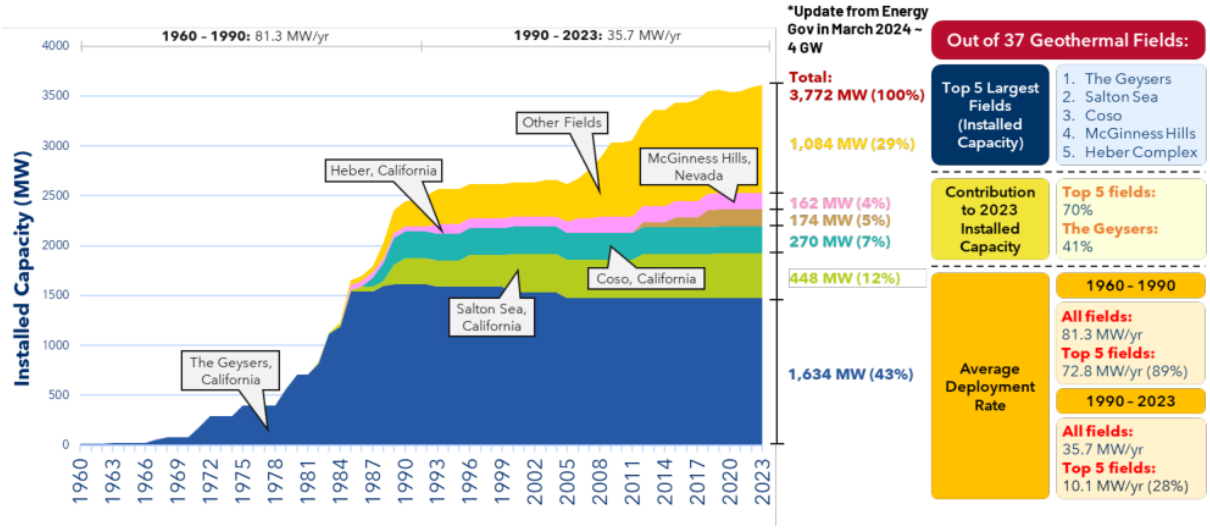

Figure 6: Historical Installed Capacity Based on Field Location.

As the global energy landscape continues to evolve, the role of geothermal energy is expanding beyond traditional electricity generation. Innovative business models are emerging that leverage the full potential of geothermal resources, offering diverse applications and revenue streams.

Figure 7 showcases the diverse business models for geothermal energy that have emerged globally, emphasizing both conventional and innovative applications. The diagram is divided into two primary segments: Power Generation and Beyond Electricity Generation, each encompassing various strategies and technologies to maximize the utilization of geothermal resources. By embracing these innovative business models, geothermal energy can significantly contribute to global energy sustainability goals. The diverse applications highlight the potential for geothermal energy to not only provide reliable electricity but also to drive economic growth through its varied and adaptable uses. This multifaceted approach ensures that geothermal energy remains a vital component of the global transition to a sustainable energy future.

As the geothermal industry evolves, it has become imperative to explore and implement next-generation technologies that can tap into a broader spectrum of geothermal resources. These advancements aim to overcome the limitations of conventional hydrothermal systems, thereby expanding geothermal energy's reach and potential. Figure 8 illustrates the three primary categories of geothermal power generation: conventional hydrothermal, Enhanced Geothermal Systems (EGS), and closed-loop geothermal systems. Each category represents a step towards achieving greater scalability and efficiency in geothermal energy production.

The integration of these next-generation technologies marks a paradigm shift in geothermal energy utilization, allowing for a broader and more efficient exploitation of geothermal resources. By overcoming the limitations of conventional systems, EGS and closed loop technologies pave the way for geothermal energy to become a cornerstone of sustainable energy systems worldwide. These advancements support the strategic expansion of geothermal energy, contributing significantly to the goal of achieving a net-zero carbon future.

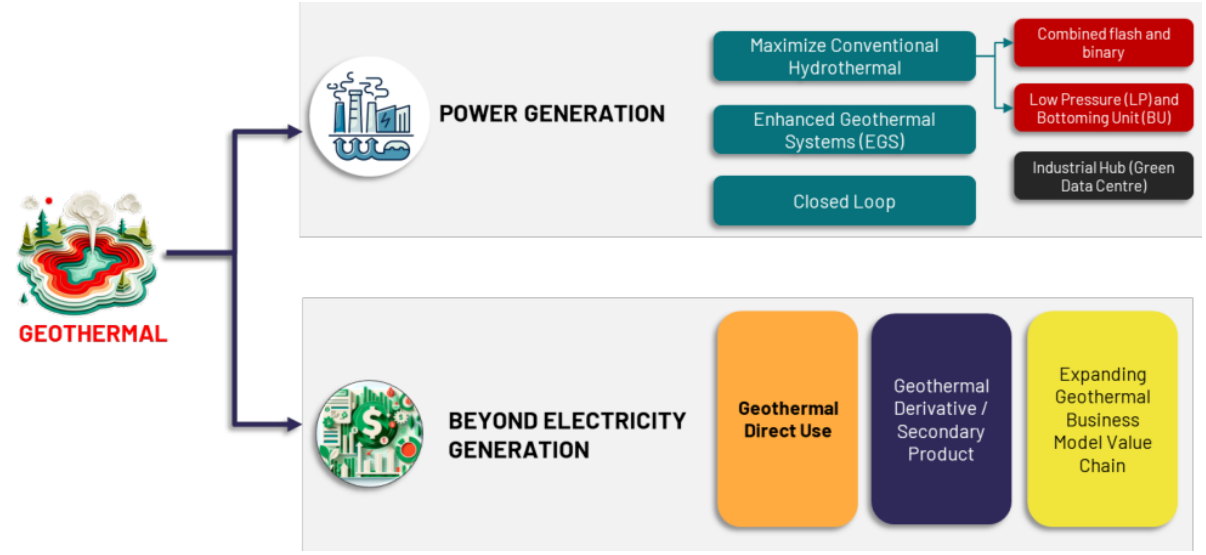

Figure 7: Geothermal Business Model Option that Currently Emerged Globally.

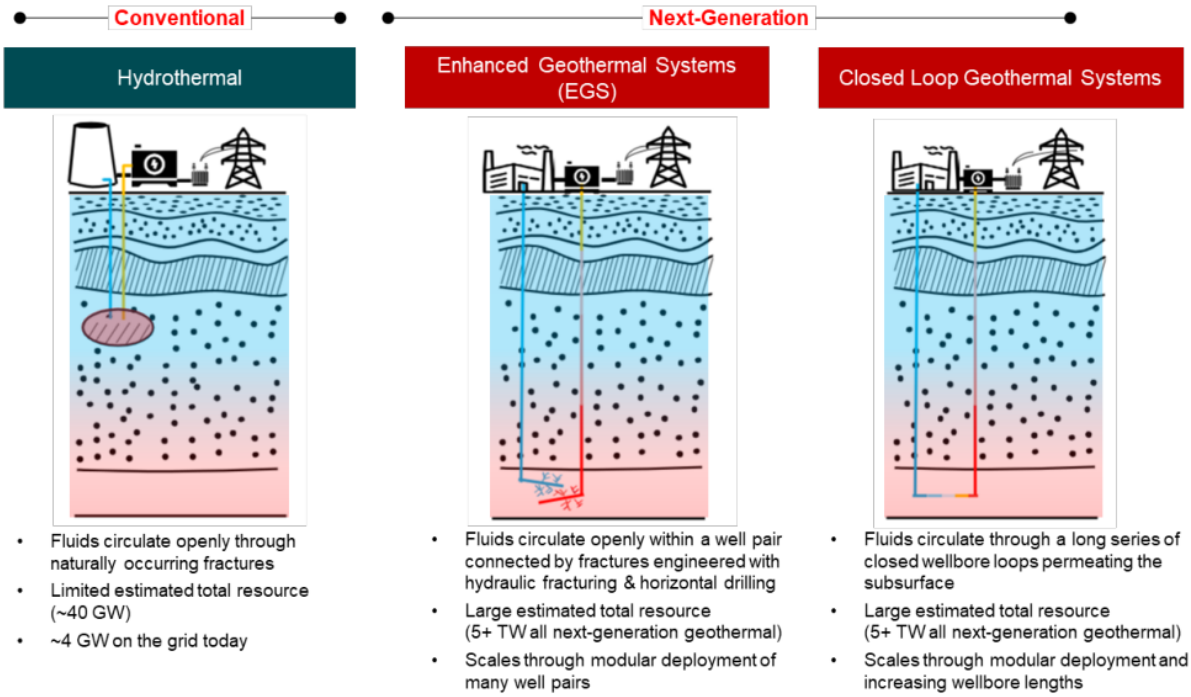

Figure 8: Next-generation geothermal technologies engineer their own resources (Achieving Scale) Modified from (US DOE, 2024).

Having discussed the technological advancements in geothermal energy, it is crucial to consider the strategic roadmap that the United States has outlined to scale these innovations across the country. The following section delves into the phased approach planned for expanding the geographic reach of next-generation geothermal technologies. Figure 9 outlines a strategic roadmap for the large-scale deployment of next-generation geothermal technologies in the United States, structured in two major stages: "Reaching Liftoff" and "Achieving Scale." This phased approach aims to systematically prove the market potential and expand the geographical reach of geothermal energy, ensuring a comprehensive and sustainable integration into the national energy mix.

4. CURRENT OPTION FOR GEOTHERMAL BEYOND ELECTRICITY

While geothermal energy is traditionally associated with electricity generation, its potential extends far beyond this conventional application. Innovative technologies and business models are emerging that exploit geothermal resources for a variety of direct-use applications, creating new revenue streams and enhancing sustainability. This section explores the current options for utilizing geothermal energy beyond electricity production, highlighting

the diverse ways in which geothermal resources can be harnessed to provide heating, cooling, and valuable by-products such as minerals and industrial applications.

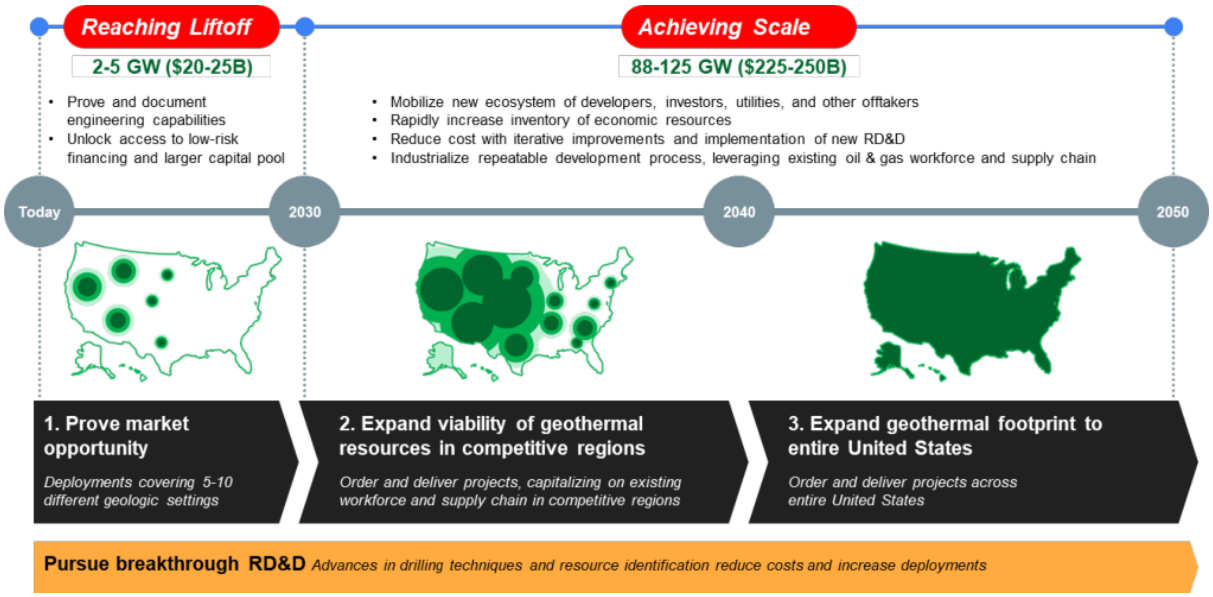

Figure 9: Scale for next-generation geothermal can proceed in two stages with increasing geographic reach in United States Modified from (US DOE, 2024).

The utilization of geothermal energy beyond electricity generation encompasses a wide range of direct-use applications that capitalize on the inherent thermal properties of geothermal resources. These applications provide significant economic and environmental benefits, contributing to the diversification and resilience of energy systems. One of the primary direct-use applications of geothermal energy is district heating, where hot water from geothermal sources is distributed through a network of pipes to heat residential, commercial, and industrial buildings. This method is highly efficient, reducing the need for fossil fuel-based heating systems and lowering greenhouse gas emissions. Countries such as Iceland and New Zealand have successfully implemented extensive geothermal district heating networks, demonstrating the feasibility and benefits of this approach.

In addition to district heating, geothermal energy can be used for greenhouse heating, aquaculture, and industrial processes. Greenhouse heating with geothermal energy allows for year-round agricultural production, even in cold climates, by maintaining optimal growing temperatures. Similarly, geothermal aquaculture supports the farming of fish and other aquatic species by providing a stable and warm water environment, enhancing growth rates and productivity.

Innovative technologies are also being developed to extract valuable minerals from geothermal brines, such as lithium, silica, and other elements. The extraction of lithium from geothermal brines, for example, presents a sustainable method to meet the increasing demand for this critical component in batteries for electric vehicles and renewable energy storage. The Salton Sea geothermal field in California is a notable example, where projects are underway to develop commercial-scale lithium extraction facilities.

Geothermal energy can also power industrial applications and support the development of eco-industrial parks. These parks integrate multiple industrial processes that utilize geothermal heat, creating synergies and reducing overall energy consumption. Examples include using geothermal energy for drying agricultural products, pasteurizing dairy products, and other heat-intensive industrial activities. This approach not only enhances the efficiency of individual processes but also promotes the sustainable development of industrial activities.

As geothermal energy continues to gain traction as a sustainable and versatile resource, its applications are expanding beyond traditional electricity generation. Innovative uses of geothermal energy are emerging worldwide, offering additional revenue streams and enhancing the overall economic viability of geothermal projects. Figure 10 illustrates the diverse array of applications for geothermal energy beyond electricity generation, highlighting how these innovations can create new revenue opportunities for geothermal companies. The figure is divided into three main categories: Geothermal Direct Use, Geothermal Derivative Products, and Expanding Geothermal Business Model Value Chain. By exploring these diverse applications, geothermal companies can tap into new markets and revenue streams, enhancing their economic resilience and contributing to global sustainability goals.

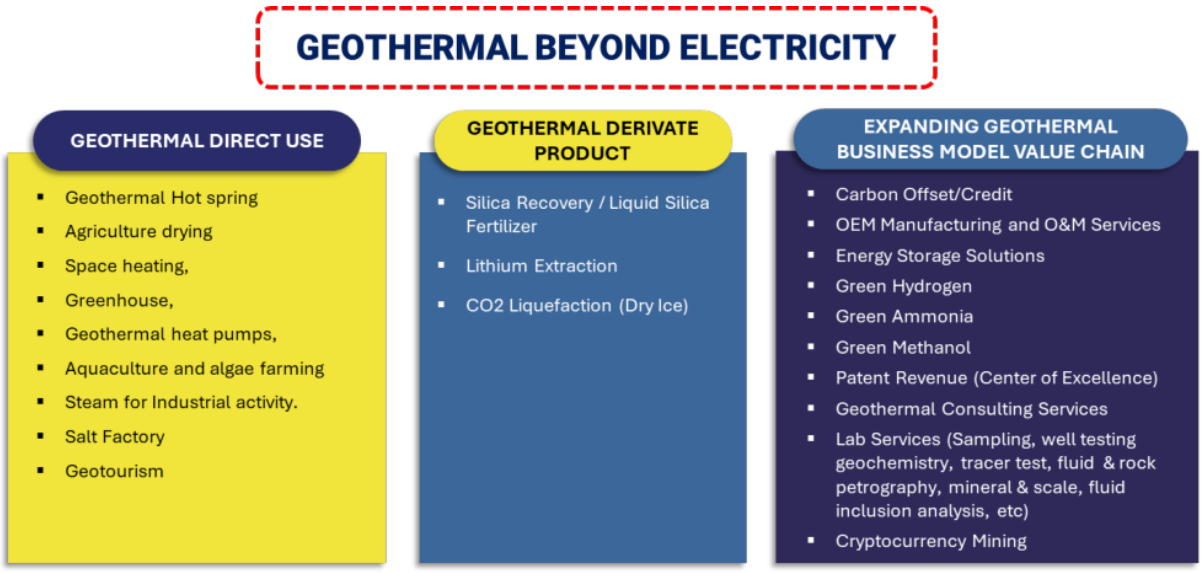

Figure 10: Identified Beyond Electricity Innovation Worldwide for Adding Additional Revenue for Geothermal Company

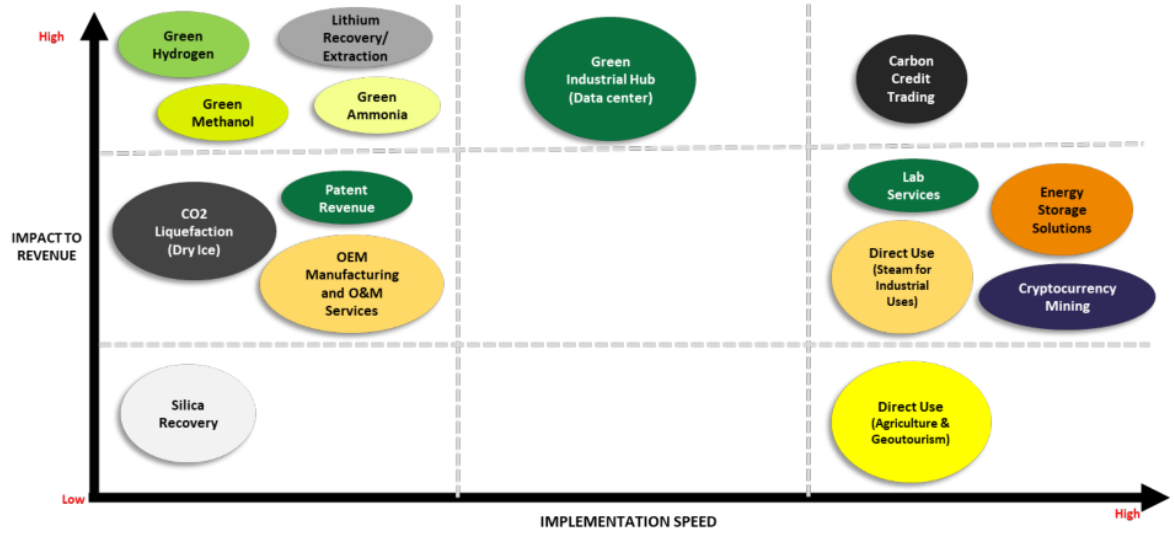

Figure 11: Preliminary Assessment on Geothermal Beyond Electricity Option.

Beyond electricity generation, geothermal energy in the U.S. has given rise to a variety of geothermal value chain and derivative products that offer additional economic and environmental benefits. These include direct heating applications, such as district heating systems, greenhouse heating, and aquaculture, which utilize the heat directly from geothermal sources. Innovative technologies are also being developed to extract valuable minerals like lithium from geothermal brines, presenting new revenue streams and contributing to the sustainability of geothermal operations. The development of these derivative products reflects a growing recognition of the multifaceted value of geothermal resources, expanding the industry's potential beyond mere power production.

By understanding these elements of the geothermal business model in the U.S., this section sets the stage for discussing the potential applications and strategies for Indonesia, leveraging the insights and successes from a well-established geothermal market to foster similar growth and sustainability in a different geographic and economic context.

After examining the diverse applications of geothermal energy beyond electricity generation, it is essential to assess these options in terms of their potential impact and feasibility. Figure 11 offers a preliminary assessment of various geothermal applications beyond electricity generation, plotted on a matrix that considers both feasibility and potential impact. This visual representation aids in understanding which applications are most viable and impactful, guiding strategic decision-making for stakeholders in the geothermal industry.

This assessment highlights the diverse opportunities for utilizing geothermal energy beyond electricity generation. By identifying applications with the highest feasibility and impact, stakeholders can prioritize investments and development efforts, maximizing the benefits of geothermal resources and contributing to sustainable energy and economic growth.

The expansion of geothermal applications beyond electricity generation represents a significant opportunity to diversify and strengthen the geothermal business model. By integrating direct-use applications and derivative products into the geothermal value chain, stakeholders can create new revenue streams and enhance the overall economic viability of geothermal projects. This holistic approach aligns with global trends towards sustainable and circular economies, where maximizing resource efficiency and minimizing waste are paramount.

In short, the current options for geothermal energy beyond electricity offer a multitude of benefits and opportunities. By leveraging these diverse applications, geothermal energy can play a pivotal role in achieving sustainability goals, reducing reliance on fossil fuels, and fostering economic growth through innovative and efficient use of natural resources.

4.1 The Position of Geothermal Derivative Products in the U.S. Geothermal Business Models

The integration of geothermal derivative products into the U.S. geothermal business models marks a strategic evolution from traditional electricity generation to a broader, more diversified utilization of geothermal resources. This shift not only enhances the economic viability of geothermal projects but also aligns with broader environmental and sustainability goals.

Geothermal derivative products represent a significant economic opportunity. These applications directly utilize the thermal energy from geothermal sources without the intermediary step of electricity generation, reducing energy loss and increasing efficiency. In regions like the Pacific Northwest and parts of California where geothermal activity is high, these uses have been integrated into local economies, providing heat for homes, businesses, and agricultural operations.

The expansion into derivative products enhances the environmental appeal of geothermal energy. By using geothermal heat directly, these applications avoid the emissions associated with burning fossil fuels for heating purposes. Moreover, the extraction of minerals such as lithium from geothermal brines presents an opportunity to support the growing renewable energy sector, particularly in battery production for electric vehicles, without the extensive environmental impact associated with traditional mining processes.

U.S. policy frameworks have increasingly recognized and supported the development of geothermal derivative products. Initiatives and incentives aimed at reducing carbon footprints and promoting renewable energy use have facilitated the growth of this sector. Policies that streamline permitting processes and provide financial incentives for the development of both geothermal power and its derivatives are crucial for the sector's growth.

The technological innovation surrounding geothermal derivative products is a key aspect of their position in U.S. business models. Advanced technologies that allow for the efficient extraction of heat and minerals from geothermal fluids are being developed and refined, further expanding the potential applications of geothermal energy. Research and development efforts supported by both government and private sectors are vital in overcoming the technical challenges associated with these innovations.

The strategic importance of geothermal derivative products in U.S. business models cannot be overstated. By diversifying the applications of geothermal energy, businesses can reduce risk, increase resilience, and tap into new markets. This diversification also aligns with global trends towards sustainability and the circular economy, where maximizing resource efficiency is key.

In short, geothermal derivative products are positioned as both a complement and a significant enhancement to the traditional geothermal business model in the United States. They provide a pathway to not only economic diversification but also to achieving sustainability and environmental goals, thereby reinforcing the strategic value of geothermal energy in the renewable energy landscape. This multifaceted approach not only solidifies the role of geothermal energy in the current market but also ensures its relevance and expansion in the future energy scenarios.

5. LESSON LEARNED FROM UNITED STATES FOR IMPLEMENTATION IN INDONESIA

The United States has long been a pioneer in geothermal energy development, not only for electricity generation but also for a multitude of direct-use applications and derivative products. These innovative approaches have demonstrated significant economic and environmental benefits, providing valuable lessons for other countries with geothermal potential, such as Indonesia. This section focuses on the key lessons learned from the U.S. experience in geothermal applications beyond electricity generation and explores how these strategies can be effectively implemented in Indonesia to maximize the value of its geothermal resources.

The U.S. has successfully harnessed geothermal energy for a range of applications beyond electricity generation, offering a wealth of insights that can be adapted for Indonesia's geothermal sector. Key lessons from the U.S. experience highlight the importance of technological innovation, supportive policy frameworks, and strategic market development.

- **Market Development and Diversification**: The U.S. has already diversified its geothermal market by integrating geothermal energy into various sectors, creating multiple revenue streams. Direct-use applications such as district heating, aquaculture, and industrial heating have proven economically viable and environmentally beneficial. Indonesia can adopt a similar approach by promoting the integration of geothermal energy into non-electrical applications. Encouraging the development of geothermal greenhouses, aquaculture farms, and industrial parks can create new economic opportunities and enhance the sustainability of energy use.
- **Geothermal Derivative Products**: The extraction of valuable minerals from geothermal brines, such as lithium and silica, has emerged as a significant revenue stream in the U.S. The Salton Sea geothermal field in California exemplifies how geothermal operations can be coupled with mineral extraction to enhance economic viability. Indonesia, with its rich geothermal resources, can explore the potential for extracting minerals from geothermal fluids, adding value to geothermal projects and supporting the growth of related industries, such as battery production for electric vehicles.
- **Community and Environmental Benefits**: Geothermal direct-use applications provide substantial community and environmental benefits. The U.S. experience shows that geothermal district heating can significantly reduce greenhouse gas emissions and provide affordable heating solutions for communities. In Indonesia, implementing geothermal district heating systems can improve air quality and reduce reliance on fossil fuels, contributing to national sustainability goals and enhancing the quality of life for local populations.

By learning from the U.S. experience, Indonesia can develop a comprehensive strategy for utilizing geothermal energy beyond electricity generation. Adopting advanced technologies, creating supportive policy frameworks, diversifying market applications, exploring derivative products, and emphasizing community and environmental benefits will enable Indonesia to maximize the value of its geothermal resources. These efforts will not only support economic growth but also contribute to Indonesia's commitment to sustainable development and climate change mitigation.

6. CONCLUSION AND PATH FORWARD

The utilization of geothermal energy beyond electricity generation offers Indonesia a valuable opportunity to harness its geothermal resources for diverse applications. By learning from the U.S. experience and implementing strategic measures, Indonesia can unlock the full potential of its geothermal resources, fostering sustainable economic development and contributing to a resilient and low-carbon energy future. The path forward requires coordinated efforts, strategic investments, and a commitment to exploring and developing geothermal applications that extend beyond traditional power generation.

Based on the study results, several paths forward that can be drawn are summarized as follows:

- *Policy and Regulatory Support*: Establishing supportive policies and regulations that encourage investment in geothermal beyond electricity applications. This includes incentives for research and development, financial support for pilot projects, and streamlined permitting processes.
- *Collaboration and Partnerships*: Building partnerships between government agencies, industry stakeholders, and research institutions to advance geothermal technologies and applications. Collaborative efforts can facilitate knowledge sharing, resource pooling, and the development of innovative solutions.
- *Investment in Research and Development*: Prioritizing research and development to advance geothermal technologies and geothermal beyond electricity generation option. Investment in R&D will drive technological advancements and enhance the viability of new applications.
- *Public Awareness and Education*: Raising awareness about the benefits of geothermal energy beyond electricity generation through public education campaigns and community engagement. This will help garner support for geothermal projects and promote broader acceptance of geothermal technologies.

It is important to note that this study is preliminary, and a more detailed analysis of each aspect is required before proceeding to pilot implementation or commercial-scale application in Indonesia. Additionally, this study is still in the drafting stage; further elaboration, revisions, and additional explanations will be incorporated as the work progresses.

Utilizing Geothermal Resources for Green Ammonia Production: A Techno-Economic Analysis for Decarbonizing Coal Power Plants in Indonesia

Annisa N Hidayah[1], Danny Kusuma[1], Yudithia Prastika[2], and Koichi Yamashita[3]

[1]Aarunya Mitra Optima
[2]PT Sarana Multi-Infrastuktur (Persero)
[3]Global Challenge

Keywords: Geothermal, Green Ammonia, Ammonia Co-firing, CFPP Early Retirement

ABSTRACT

Indonesia boasts abundant geothermal potential, with estimates exceeding 20GW, as per data from the Ministry of Energy and Mineral Resources (MEMR). However, current exploitation remains relatively modest, with only around 2GW utilized, highlighting a significant untapped resource, particularly in Eastern Indonesia. Yet, in remote areas, where geothermal potential is rich, electricity demand often falls below the typical capacity of geothermal plants, rendering development economically infeasible or leading to oversized installations with excess capacity.

This paper explores an innovative solution to this challenge by leveraging geothermal energy not solely for electricity generation but also for the production of secondary products, notably green energy carriers, i.e., green ammonia for this study. Recent technological advancements have enabled the utilization of green ammonia as a clean alternative fuel, suitable for co-firing in coal power plants, offering a pathway to decarbonize Indonesia's energy mix.

On the other hand, Indonesia's Net Zero Emissions (NZE) plan not only to develop more new and renewable energy, but also to include an early retirement program for Coal Fired Power Plants (CFPPs). The paper investigates the comparative merits of two decarbonization strategies.

Firstly, it examines the conventional approach of CFPP early retirement, which aims to reduce emissions from the power sector. However, some analyses have raised concerns about the economic viability and substantial costs associated with this strategy. Under this paper, the CFPP retirement age is assumed mid-range around 15-20 years and the DCF method is used to understand the remaining value estimation.

In comparison, the paper proposes an alternative approach: utilizing excess geothermal capacity to produce green ammonia for co-firing in existing CFPPs. Excess electricity of the geothermal power plant could be utilized in an ammonia plant where the product, green ammonia, is then transported to the target CFPPs for co-firing.

By conducting a comprehensive techno-economic analysis, the study seeks to provide stakeholders with insights into the comparative cost-effectiveness of these strategies. The anticipated findings not only offer guidance on the most economically viable pathway for decarbonizing CFPP but also stimulate discussions on maximizing geothermal utilization by improving financial viability of geothermal project, especially in Eastern Indonesia. Furthermore, the paper will propose policy implications derived from the analysis results, which could serve as a foundation for informed decision-making in the power and geothermal sectors, aligning with Indonesia's broader sustainable development goals.

1. INTRODUCTION

The global shift towards sustainable energy has sparked a significant interest in hydrogen, particularly green hydrogen, which is produced through the electrolysis of water using renewable energy (RE) sources (IEA, 2019). Indonesia, with its vast RE potential, especially in geothermal energy estimated at around 29 gigawatts (GW) (Darma, 2021), stands at the forefront of this transition. However, in eastern Indonesia, many energy reservoirs remain unutilized or underutilized due to low demand.

Indonesia's power generation is predominantly coal-based, contributing to around 61.55 percent of the nation's electricity mix as of 2022 (Statista, 2022). To align with the Net Zero Emissions (NZE) target, the Government of Indonesia (GoI) has initiated an early retirement program for coal-fired power plants (CFPPs), phaseout of CFPP by 2056 and no coal usage beyond 2030 (Cui & Tumiwa, 2022). This transition, while environmentally crucial, comes with substantial costs. Retiring young assets before the end of their operational lifetime leads to lost revenue and potential legal complexities, especially in cases where Independent Power Producers (IPPs) are

bound by Power Purchase Agreements (PPAs) with take-or-pay clauses. In addition, it is estimated that around USD 4.6 billion is required for Indonesia to fund and meet the cost of CFPPs retirement by 2030 (IESR, 2022).

In response to these challenges, Indonesia is exploring innovative technologies such as ammonia co-firing in CFPPs. Ammonia, when burned, does not produce CO_2, making it an attractive option for co-firing with coal and reducing the carbon footprint of existing power plants (Yamashita & Urakata, 2023). For instance, a 20% co-firing ratio means ammonia replaces 20% of coal by energy content. Mitsubishi Heavy Industries, Ltd. (MHI) is among the companies developing technologies to enable ammonia co-firing in both circular firing and opposed firing systems of coal-fired boilers (Yamashita & Urakata, 2023). In addition, JERA, Japan's biggest power generator, recently completed a groundbreaking three-month 20% ammonia co-firing with coal trial at its Hekinan Thermal Power Station in central Japan with promising outcomes. Notably, nitrogen oxide (NOx) levels remained unchanged compared to coal-only firing, sulfur oxide emissions decreased by 20%, and nitrous oxide—a potent greenhouse gas—was undetectable (Obayashi, 2024). While this technology is still in its nascent stages, it represents a promising step towards Indonesia's commitment to a cleaner, more sustainable energy future.

Ammonia can be produced in many ways resulting in the different colors of ammonia, such as grey, blue and green ammonia. Grey ammonia is produced from natural gas without any carbon capture and storage (CCS) while blue ammonia incorporates CCS for its by-products. At the same time, green ammonia is produced using green hydrogen generated by water electrolysis, powered by renewable energy. Geothermal energy is aimed to be used for this purpose as the source of renewable energy. Currently, Pertamina NRE collaborates with Tokyo Electric Power Company Holdings (TEPCO HD) on green hydrogen and green ammonia development using geothermal (Pertamina, 2022). The remaining heat from separated geothermal brine from Ulubelu Geothermal Power Plant Unit 1-4 is used to an integrated geothermal bottoming Organic Rankine Cycle (ORC) Binary Plant and electrolysis (Brilian, Khasani, Mubarok, Ruliandi, & Firmansyah, 2022). Interestingly, the usage of excess power (during nighttime) from the geothermal power plants in eastern Indonesia could be a game-changer due to very low demand while literature on this specific case is scarce, the potential impact is immense. If successful, this unique case could demonstrate the viability of geothermal-based ammonia production and contribute to cleaner energy solutions. Therefore, the objective of this study is to assess the economic feasibility of producing green ammonia from geothermal sources and apply it to reduce emissions by co-firing it to existing CFPPs.

2. CASE COMPARISON

Under this study, we assume that the CFPP is owned by PT PLN (Persero) or its subsidiaries. The assumed capacity for the CFPP is 400 MW. This number is selected based on the averaged capacity of some CFPPs that are ranging between 100 – 800 MW (see Table below) which were also identified to be easily achievable plants for swift shutdown, contributing to the GoI's plan reach NZE (Cui & Tumiwa, 2022). The potential CFPP age to be phased out by the GoI is 15 years old and assumed remaining period to operate is 25 years.

Table 1: List of CFPPs equipped with sub-critical technology.

Plant	Area	Capacity (MW)	COD Year	Technology
Bukit Asam Muara Enim	South Sumatera	260	1987	Subcritical
PLN Paiton	East Java	800	1994	Subcritical
Ombilin	West Sumatera	200	1996	Subcritical
Asam-asam	South Kalimantan	260	2000	Subcritical
Cilacap Sumber	Central Java	600	2006	Subcritical
Tarahan	Lampung	100	2007	Subcritical
Bangka Baru	Bangka-Belitung	60	2014	Subcritical
Merak	Banten	120	2014	Subcritical
Cikarang	West Java	280	2017	Subcritical
Tabalong	South Kalimantan	200	2019	Subcritical

2.1 Technology Comparison

For case comparison, we designed two hypothetical cases to compare the economic impacts:

2.1.1 Case 1 - Early Retirement of CFPP and Replacement with Renewable Energy (RE) Power Plant

This study replicates the Asian Development Bank's (ADB) Energy Transition Mechanism (ETM) initiative, focusing on the premature decommissioning of Cirebon-1, Coal-Fired Power Plant (CFPP) in Indonesia, slated for retirement 7 years ahead of schedule (ADB, 2023). Alongside the cessation of operations at the CFPP, PT PLN is urged to facilitate the establishment of a Renewable Energy (RE) power facility to offset the resultant

electricity deficit. To facilitate comparative analysis, the RE power plant's annual electricity generation must be commensurate with that of the CFPP.

2.1.2. Case 2 - Retrofitting Existing CFPP into Co-firing with Green Ammonia

In this scenario, the CFPP undergoes retrofitting to enable cofiring with green ammonia produced using the Haber-Bosch and electrolysis processes, powered sustainably by a geothermal plant. To ensure emissions comparability, the green ammonia production capacity is designed to match the energy output equivalent of one unit of CFPP, with cofiring at 20% of its Lower Heating Value (LHV). Consequently, the produced ammonia is sufficient to supply five units of CFPPs, each cofiring at 20%.

The ammonia production facility is assumed to be situated near the port, with electricity sourced from a geothermal plant delivered via PT PLN's existing transmission infrastructure. The ammonia, produced in liquid form, is then transported by shipping to the designated CFPP. Upon arrival at the port of destination, the ammonia is stored, regasified, and piped to the CFPP. The CFPP's boiler is modified to accommodate ammonia gas combustion, which necessitates retrofitting with flue gas treatment to ensure NOx emissions remain within permissible environmental standards.

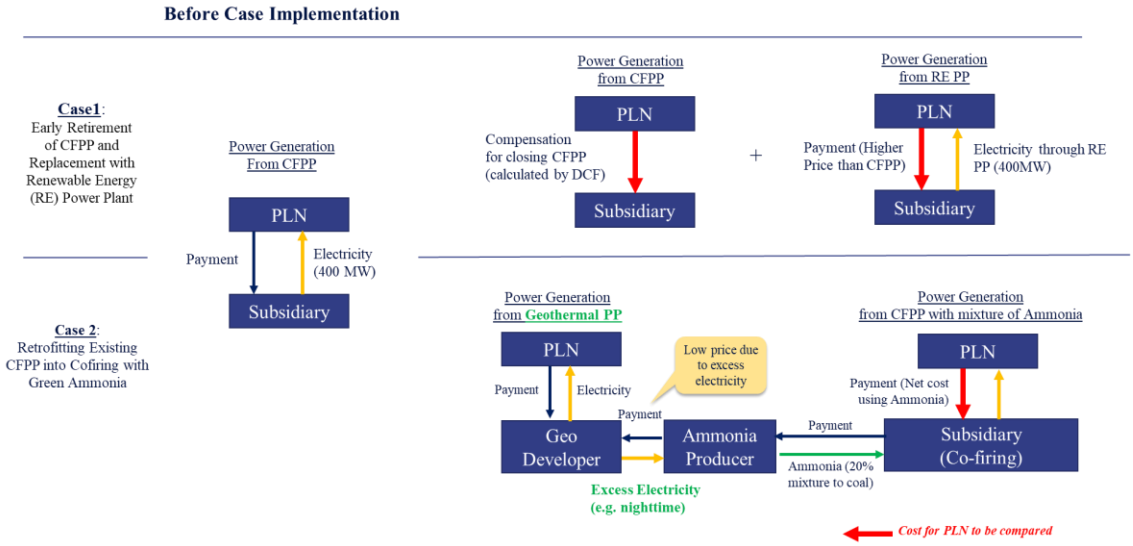

Figure 1: Money flow of hypothetical case comparison.

2.2 Cash Flow Comparison

Based on above case comparison, the cash flow is as follows

2.2.1 Case 1 - Early Retirement of CFPP and Replacement with Renewable Energy (RE) Power Plant

The premature closure of a power plant entails forfeiting potential future cash flows equivalent to the remaining economic value of the plant. The cash flow analysis for the operation of a CFPP assumes revenue derived from electricity sales, calculated as the Power Purchase Agreement (PPA) tariff multiplied by annual electricity generation. For the CFPP, a PPA tariff of USD 60/MWh is assumed. During operation, expenses include the cost of coal supply and operating expenditures (OPEX). The delivered price of coal is assumed to be USD 50/ton for sub-bituminous coal with an energy density of 20 MJ/kg LHV. Additionally, at year zero, costs associated with plant removal are incurred.

In parallel, PT PLN incurs costs related to the development of a Renewable Energy (RE) power plant as a replacement. For simplicity, this cost is assumed to align with the Levelized Cost of Electricity (LCOE) of a solar PV and battery system, set at USD 90/MWh.

2.2.2. Case 2 - Retrofitting Existing CFPP into Co-firing with Green Ammonia

In the case of co-firing, PT PLN incurs costs associated with retrofitting the CFPP to enable ammonia cofiring. Limited cost data is available due to the evolving nature of the technology. An analysis by IEEJ estimates a capital expenditure (CAPEX) of USD 224 million for achieving 20% co-firing capacity in a 700 MW plant (IEEJ, 2022). Conversely, operational expenditures (OPEX) for the retrofitted plant are assumed to remain comparable to those of a non-retrofitted plant for simplicity and are thus excluded from the cash flow calculations.

Another significant aspect of the cash flow analysis for the co-firing scenario is the procurement cost of green ammonia. The delivered cost of ammonia is assumed to encompass production and transportation expenses. For

instance, transportation costs for ammonia over a distance of 2000 km from eastern Indonesia to CFPPs in Java and Sumatra are estimated at USD 15.43/ton (Nayak-Luke, et al., 2021).

Moreover, ammonia production involves costs associated with hydrogen electrolysis and the Haber-Bosch process. According to the International Energy Agency (IEA), the cost of electrolysis-based hydrogen and subsequent ammonia production is influenced by electricity prices and plant operating hours. Utilizing geothermal electricity ensures high plant utilization during peak hours, potentially reducing the levelized production cost. Assuming nighttime geothermal electricity costs of USD 10/MWh due to low demand, hydrogen production costs could decrease to approximately USD 1/kg, making ammonia production competitive with grey hydrogen derived from natural gas. Consequently, the production cost of ammonia is estimated at USD 200/ton (IEA, 2019).

As a consequence of co-firing with ammonia, the CFPP owner reduces coal consumption by 20%. However, due to ammonia's lower energy density of 19 MJ/kg LHV, the quantity of ammonia required for co-firing is slightly greater than the reduction in coal mass.

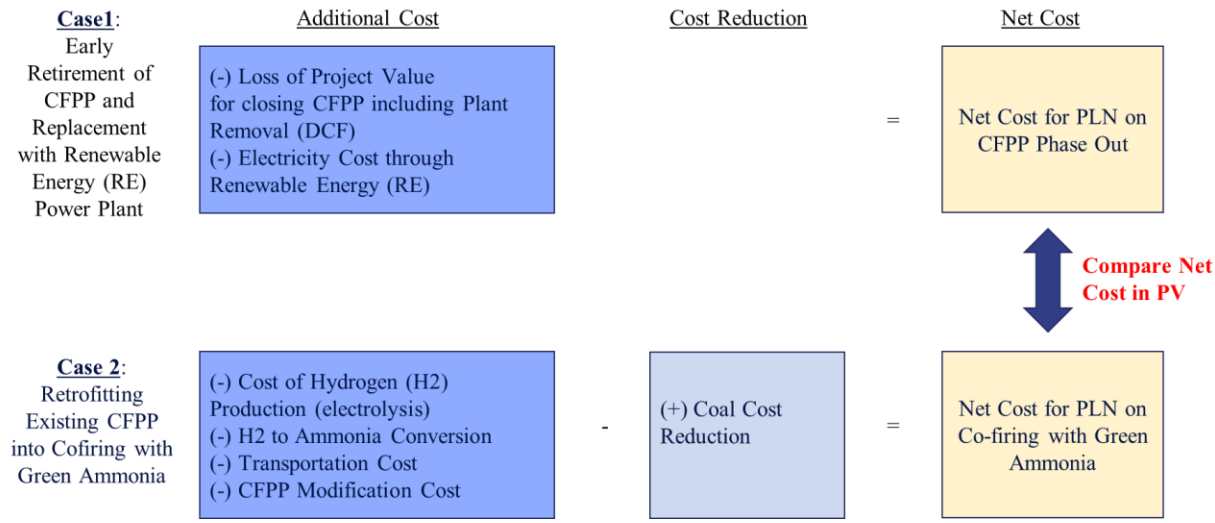

Figure 2: Cash flow comparison of the hypothetical cases.

3. METHODOLOGY AND ASSUMPTIONS

3.1 Economic Analysis Methodology

The lifecycle net cost of Case 1 and 2 was evaluated and the viewpoint of PT PLN was compared. The lifecycle net costs of Case 1 and 2 were converted into present value by using discount rate. For Case 1, the loss of project value for closing CFPP including plant removal was estimated by using Discounted Cashflow (DCF) method. DCF method is typically used to assess corporate value considering future free cash flow of the company with the following formula.

$$\text{DCF} = \frac{(\text{Year 1 FCF})}{(1+\text{discount rate})} + \frac{(\text{Year 2 FCF})}{(1+\text{discount rate})^2} + \frac{(\text{Year 3 FCF})}{(1+\text{discount rate})^3} + \cdots$$

$$\text{Free cash flow (FCF)} = \text{Operating Cash Flow} + \text{Investing Cash Flow}$$

3.2 Assumptions

3.2.1 Parameter Value

Table 2 summarizes the key assumptions and settings for the projects.

4. RESULT AND ANALYSIS

4.1 Calculation Result

By calculating the parameter value described in Section 3.2 using the methodology outlined in Section 3.1, it was found that the total Net Present Value (NPV) for the total cost of implementing Case 2 (retrofitting an existing CFPP to co-fire with green ammonia) is lower than that of Case 1 (early retirement of CFPP and replacement with RE Power Plants). This result is based on the assumption that the ammonia used for co-firing is produced using excess electricity from a geothermal power plant, with an assumed very low price of 1 cent/kWh. Additionally, Case 2 assumes the use of RE from solar power plants, with a current average PPA price of approximately 6

cents/kWh. The results may vary if these assumptions are adjusted. Therefore, a sensitivity analysis is performed in Section 4.2 to understand the effect of changing these parameters.

Table 2: List of assumptions.

Parameters	Value	Assumptions and References
CFPP		
Capacity	400 MW	-
Age	25 years	-
Remaining lifetime	15 years	-
Plant efficiency	35%	-
Coal price	USD 50/ton	Coal ceiling price for PLN
Plant capacity factor	85%	-
Plant retrofit (cofiring) cost	USD 224 million/700 MW	(IEEJ, 2022)
Plant decommissioning cost	USD 10,000/MW	(Malley, 2016)
Plant fixed OPEX	USD 40,000/MW/year	(EIA, 2020)
Plant variable OPEX	USD 4.5/MWh	(EIA, 2020)
LCOE of RE replacement powerplant	USD 90/MWh	(IESR, 2021)
Ammonia production and transportation		
Electricity supply price	USD 10/MWh	Excess electricity from geothermal power plant, e.g., low demand at night nighttime
Ammonia production cost	USD 200/ton ammonia	(IEA,2019)
Ammonia transport cost	USD 15.4 / ton ammonia	Distance 2000 – 3000 km, assuming transporting from Eastern Indonesia to Java Island (Nayak-Luke, et al., 2021)
Financial		
Discount rate	10%	-

3.2.2 Timeline

Table 3: Case timeline assumptions.

Case 1	**Year Implemented**	**Total Year**
Operation of CFPP	Year 16	1 Year
Decommissioning of CFPP	Year 17	1 Year
Construction of RE as replacement for CFPP	Year 16	1 Year
Operation of RE	Year 17 – Year 40	24 Years
Decommissioning of RE	Year 40	1 Year
Case 2	**Year Implemented**	**Total Year**
Operation of Geothermal Power Plant	Year 16 – Year 40	25 Years
Operation of CFPP	Year 16 – Year 40	25 Years
Construction of Electrolysis & Haber Bosch	Year 16	1 Year
Construction of Cofiring Equipment at CFPP	Year 16	1 Year
Operation of Cofiring Equipment at CFPP	Year 17 – Year 40	24 Years
Decommissioning of CFPP	Year 40	1 Year

The analysis further examines the cost breakdown associated with each scenario. In the case of early retirement, the predominant cost factor is the expense incurred in substituting power supply with RE sources. It is noteworthy, however, that this cost element is expected to diminish over time concurrent with advancements in RE technology and the maturation of its market. Additionally, a significant portion of costs are attributed to the loss of FCF of existing CFPP assets. The imposition of carbon taxes may exert downward pressure on this asset value, as CFPP operators would be compelled to absorb additional expenses associated with carbon emissions during operational phases. Alternatively, installation of carbon capture technologies presents another avenue for CFPP operators, albeit at an added cost.

Conversely, the examination of the co-firing scenario reveals that the primary cost driver is the procurement of green ammonia, significantly outweighing the savings derived from reduced coal expenditures by more than fivefold. Given their comparable LHV, this implies that the cost per ton of green ammonia is five times greater

than that of coal. Furthermore, this situation is exacerbated by the assumption of a low-cost geothermal electricity supply for ammonia production at USD 10/MWh by the author. This figure starkly contrasts with the typical electricity supply prices in Indonesia, which generally range between USD50 to 100/MWh.

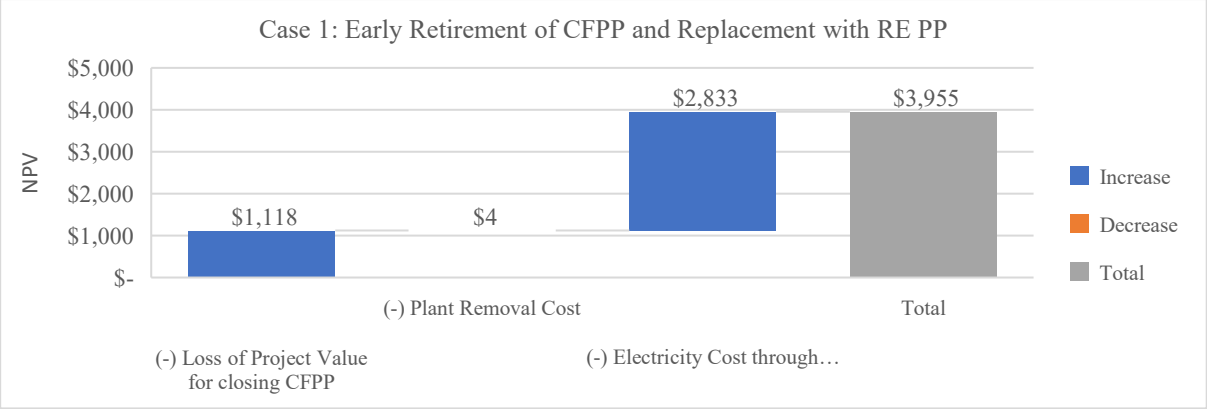

Figure 3: Cost NPV of early retirement case.

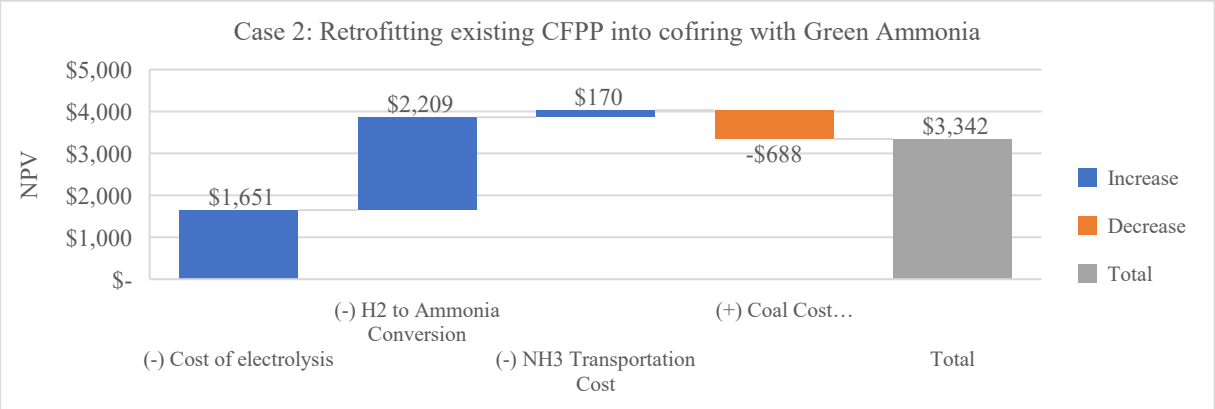

Figure 4: Cost NPV of co-firing case.
(Number shown is in Million USD)

4.2 Sensitivity Analysis

A sensitivity analysis was performed on two parameters, as summarized in the following table:

Table 4: Sensitivity analysis assumptions.

Case	Parameter Analyzed	Low	Mid	High
Case 1 - Early Retirement of CFPP and Replacement with RE Power Plant	LCOE of RE replacement powerplant	6 cents/kWh[1]	9 cents/kWh[2]	12 cents/kWh[3]
Case 2 - Retrofitting Existing CFPP into Cofiring with Green Ammonia	Electricity supply price *(from geothermal power plant)* for Ammonia Production	1 cent/kWh[4]	7 cents/kWh[5]	9.76 cents/kWh[6]

Note:
The price presented in the table above is based on the following assumptions:
[1]Indonesia's historical solar Power Purchase Agreements (PPAs) and bid prices in 2020 ranged from 5.5 to 6.3 cents per kWh (IESR, 2021).
[2]An auction for one of the first significant solar plus storage projects revealed a winning bid of 9.075 cents per kWh (IESR, 2022).
[3]The highest ceiling price for solar power plants, as stipulated by Presidential Regulation No. 112/2022, without considering location factors, is 11.5 cents per kWh.
[4]There is an assumption regarding the price of excess electricity during periods of low demand, such as nighttime (see Figure 5).
[5]The Basic Production Price (BPP) stated in the Ministry of Energy and Mineral Resources (MEMR) Decree 169.K/HK.02/MEM.M/2021 is 7.05 cents per kWh.

[6]The highest geothermal ceiling price, as outlined in Presidential Regulation No. 112/2022, without considering location factors, is 9.76 cents per kWh.

Based on the parameters set above, 9 (nine) scenarios were developed, and the results are summarized in table below.

Table 5: Sensitivity analysis result.

Scenarios	Assumptions on Parameter Value		NPV Comparison (in Million USD)	
	LCOE of RE replacement powerplant	Electricity price for Ammonia Production (From Geothermal PP)	Case 1	Case 2
Scenario A	6 cents/kWh	1.0 cent/kWh	$ 3,011	$ 3,342
Scenario B		7.0 cents/kWh	$ 3,011	$ 10,648
Scenario C		9.7 cents/kWh	$ 3,011	$ 13,936
Scenario D	9 cents/kWh	1.0 cent/kWh	$ 3,955	$ 3,342
Scenario E		7.0 cents/kWh	$ 3,955	$ 10,648
Scenario F		9.7 cents/kWh	$ 3,955	$ 13,936
Scenario G	12 cents/kWh	1.0 cent/kWh	$ 4,900	$ 3,342
Scenario H		7.0 cents/kWh	$ 4,900	$ 10,648
Scenario I		9.7 cents/kWh	$ 4,900	$ 13,936

4.3 Discussion

From the calculation results of the 9 (nine) scenarios, it can be observed that Case 2 (Retrofitting Existing CFPP to Co-fire with Green Ammonia) is only feasible when the geothermal electricity price for ammonia production is low, such as when utilizing excess power from a geothermal power plant, which is reflected in Scenarios D and G. When the geothermal electricity price for ammonia production approaches the BPP of PT PLN at 7 cents/kWh or higher, the total cost increases significantly. In such cases, it becomes more sensible to implement Case 1 (Early Retirement of CFPP and Replacement with RE PP) as a strategy for power sector decarbonization.

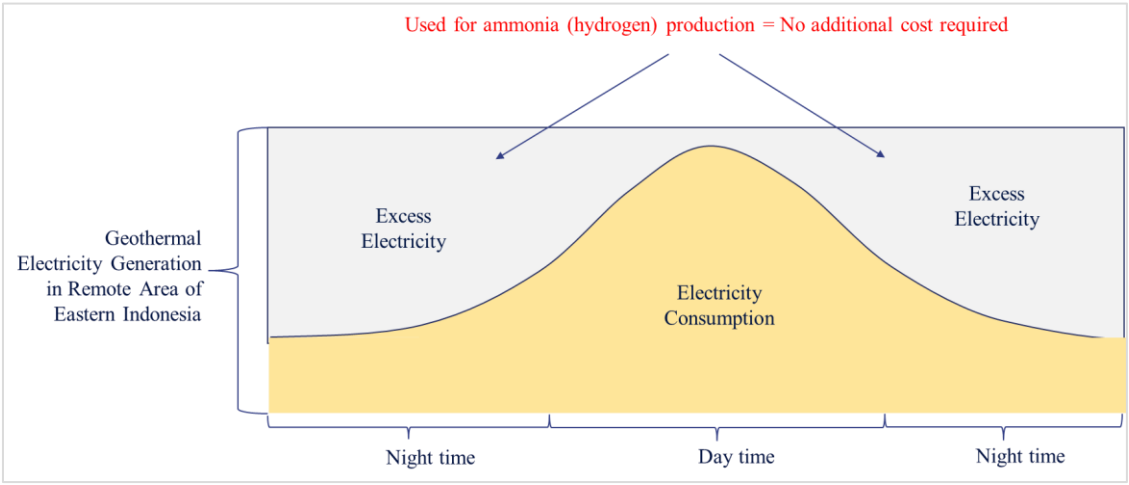

Figure 5: Geothermal powerplant electricity output profile in low demand areas.

The low geothermal electricity price for ammonia production can be achieved by utilizing excess electricity from geothermal power plants, such as during nighttime when the demand is low, as illustrated in Figure 5. Typically, geothermal power plants are set as the baseload power source, providing electricity to meet the minimum demand nearly 24 hours a day. However, if the geothermal power plant is located in sparsely populated areas with very low demand, such as in Eastern Indonesia, electricity generation may still exceed demand even after supplying the minimum nighttime load. We assume that this excess electricity would otherwise be curtailed by the power plant. Therefore, it is plausible that the owners of the power plants would be willing to sell this excess electricity at a very low price.

Utilizing excess geothermal electricity for ammonia production is also expected to maximize geothermal utilization, thereby increasing the revenue of the geothermal power plant. Therefore, the implementation of Case 2 could also contribute to improving the financial viability of geothermal projects, especially in Eastern Indonesia.

In addition, based on the sensitivity analysis results, it is determined that Case 2 exhibits increased competitiveness when the price of RE required to replace CFPP**S** exceeds 7 cents per kilowatt-hour (kWh). Consequently, Case 2 is recommended over Case 1 for regions with limited RE resource potential, which may lead to relatively higher RE prices.

5. CONCLUSION

There is a high demand for green ammonia (or hydrogen) under the net zero carbon emission policy target in Indonesia. Green ammonia production requires a large amount of electricity generated from RE (e.g., solar, wind, hydro, geothermal), which is more costly compared to electricity generated from fossil fuels. In the remote area of Eastern Indonesia, there exists considerable potential for geothermal resources. However, due to the limited demand and lack of connection to the major grid, the electricity generation capacity from geothermal resources must be set lower than the actual geothermal resource capacity. Additionally, since geothermal power plants generate a constant amount of electricity over a 24-hour period, some of this electricity cannot be fully utilized during nighttime hours.

By utilizing excess electricity generated from geothermal power plants located in remote areas that are not connected to the major grid, green ammonia (or hydrogen) could be produced at a lower cost. This approach could also address the mismatch between electricity demand and geothermal resource capacity in the remote regions of Eastern Indonesia. With such potential for low-cost green ammonia production utilizing geothermal, the current coal phaseout scenario could be further examined because ammonia co-firing may present a more economical solution for some types of CFPP in comparison with a phaseout scenario.

The findings of this study offer valuable insights for shaping policies aimed at transitioning the power sector, particularly in decarbonizing CFPPs. Co-firing with green ammonia emerges as a viable strategy for mitigating emissions from CFPPs. Specifically, sourcing green ammonia from geothermal sources presents a potentially economically competitive alternative to early retirement of CFPPs, particularly in regions where geothermal power plants are currently operating below capacity. The necessity of affordable electricity supply for green ammonia production serves as a critical benchmark for policymakers in designing pricing mechanisms for future projects in this domain.

Keywords: Geomedicine, Tampomas, Balneology, Geothermal, Surface Thermal Manifestation

ABSTRACT

Geomedicine is a branch of earth science that combines spatial information with its relevance to public health. Not only merely explain the benefits of surface geological features for health purposes, but this field also mitigates the risks posed by specific geological conditions. Geothermal manifestations are among the geological features that can be utilized in geomedicine. For decades, Indonesian communities have used the warm water from geothermal manifestations as an alternative treatment, an example includes the local community living in the vicinity of Mount Tampomas Geothermal Area. Fluid geochemistry analysis of surface thermal manifestations can deepen our understanding of the use of geomedicine.

The geothermal area of Mount Tampomas consists of warm springs and pools with temperatures ranging from 35°C to 50°C and pH levels from 6.67 to 7.93 with a Cl-HCO_3 type and Immature Water. There is Ciuyah warm spiring which contains high Total Dissolved Solid (TDS) and EC with 19,976 mg/L and 22,000 µs/cm, respectively. Local communities believe that the content of this warm water can serve as an alternative treatment. However, different conditions arise during geothermal exploration activities, where communities still misunderstand the definitions of potential benefits and risks of geothermal resources.

Instead of solely presenting geochemical analyses of Mount Tampomas, this study showcases variations in geothermal fluid geochemistry from various regions in Indonesia and provides an introductory framework for utilizing them in balneology practices. This study is also expected to serve as a means to properly enhance the public's understanding of geothermal resources.

1. INTRODUCTION

The concept of geomedicine varies significantly between geographical and geological perspectives. In geography, geomedicine is concerned with how spatial data can be used to describe and analyze the medical information of populations. This might include studying the distribution of health outcomes and healthcare resources across different regions (Davenhall, 2012). Conversely, the geological perspective of geomedicine involves examining the influence of natural elements and conditions derived from geological environments (Bowman, Bobrowsky and Selinus 2003). This perspective includes assessing the health impacts of naturally occurring elements in the soil, which can vary with the local geology and affect food grown in these soils. Additionally, it involves studying the health effects of geological events like volcanic eruptions, landslides, and earthquakes, as well as human activity resulting from specific geological conditions.

Though the concept was acknowledged just recently, it has been unconsciously applied ever since ancient times. Early civilizations recognized that an excess or deficiency of natural elements could cause diseases, and they used various elements for healing purposes. They also observed the negative impact of mining on human health (Rodriguez, Torres and Favas 2016, Bowman, Bobrowsky and Selinus 2003). Despite its long history of application, it is only in recent times that the field has been systematically studied, leading to the development of geomedicine as a formal discipline.

Understanding the interplay between geological factors and human health can lead to significant advancements in public health. By exploring how natural elements and conditions influence diseases, geomedicine helps identify health risks and develop targeted interventions. This approach also enhances the effectiveness of treatments utilizing natural resources like mineral-rich soils and waters. Bridging the gap between geology and medicine, this field has the potential to improve health outcomes and resource allocation, ultimately enhancing the quality of life for many.

One prominent aspect of geomedicine is the utilization of geothermal manifestations. Natural geothermal features, such as hot springs, have been used for therapeutic purposes for centuries due to their mineral-rich waters and unique properties. Beyond their relaxing warmth, understanding the chemistry of these waters offers insights into the geothermal activity and the overall geothermal system, as well as the health benefits of the elements contained in the water. Essential minerals for the human body can naturally derive from rock-forming minerals, which dissolve in water through physical and chemical processes, resulting in mineral-enriched water (Javed, et al. 2009). Geothermal manifestations effectively store these minerals in hot water, mud, or emitted gases (Galvez, Torres-Piles and Ortega-Rincon 2018, Shoedarto, et al. 2016, Javed, et al. 2009).

Balneology, a branch of geomedicine, studies the properties of geothermal water and its therapeutic use beyond recreation (Lazarowicz and Michalowski 2015). It emphasizes using mineral content and water temperature for relaxation and anti-inflammation. Despite its global application, the potential of balneology in Indonesia needs further exploration and study. Simultaneously, balneology addresses health risks by analyzing the release of harmful substances, enabling the development of strategies to mitigate these risks. By integrating geological insights with medical knowledge, balneology not only harnesses natural resources for health benefits but also ensures the safety and sustainability of these practices, providing a holistic approach to health and wellness that is deeply rooted in the natural environment.

In advance, this study is focused on the Mount Tampomas geothermal prospect area. Mount Tampomas is a Quaternary type B volcano located in Sumedang Regency, West Java, Indonesia, approximately 42 km northeast of Bandung city (Figure 1). Mount Tampomas is one of the areas included in the exploration zone, and a detailed 3G survey has been conducted by the Geological Agency for geoscience data acquisition as part of the government drilling program. Previous studies have described the Tampomas Geothermal system as a medium enthalpy system with an estimated reservoir temperature of 170°C ± 10°C and a liquid-dominated system (Permadi G. B., Herdianita, Amanda, Wibowo, & Putra, 2022; Iskandar, Demawan, Sianipar, Suryantini, & Notosiswoyo, 2018; Rahayudin, et al., 2018). However, social issues arose during the exploration as residents opposed the development of the geothermal project for power generation. Despite this, the local community has been utilizing the hot water around Mount Tampomas for hot spring baths or balneotherapy for several decades.

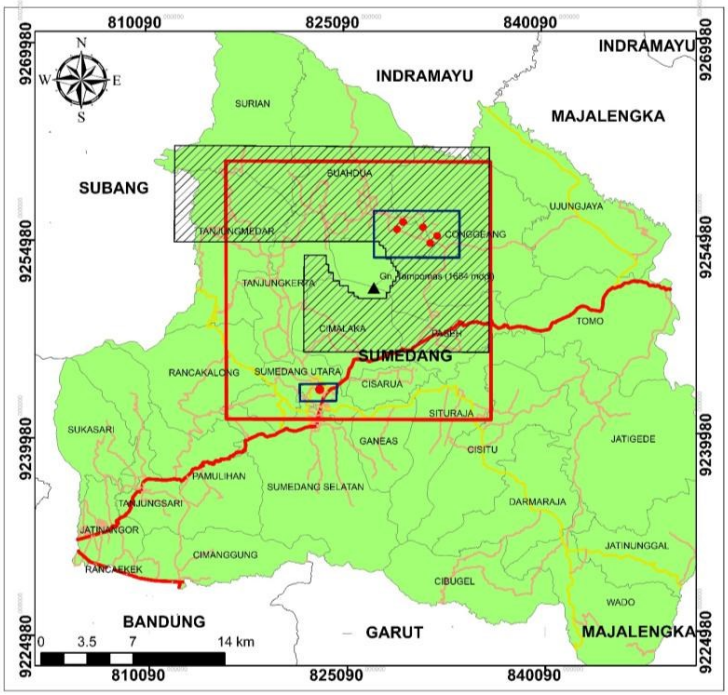

Figure 1: Location map of Tampomas geothermal area, the thermal surface manifestations distributed on the north and south of Mt Tampomas.

The primary objectives of this paper are to identify potential balneology resources at Mount Tampomas based on geochemical analysis of the water, this information will serve as a foundational reference for developing balneotherapy, specifically in Indonesia.

2. METHODOLOGY

The primary data for this research is based on geological and geochemical exploration data conducted by the Geological Agency during the 2021 survey. Using this primary data, geological analysis was carried out, producing a geological map that includes the distribution of lithology, and geological structures. The geochemical analysis of water in the study area includes basic hydrogeochemical analysis, which involves the assessment of physical parameters (pH, EC, TDS), observation of dissolved element concentrations using a Schoeller diagram, determination of water type using a Cl-SO_4-HCO_3 ternary diagram, and water equilibrium analysis based on a Na-K-Mg ternary diagram.

Based on the information obtained from the geological and geochemical conditions of the Mount Tampomas geothermal system, an analysis of the potential benefits and risks was conducted based on the total concentration of each dissolved chemical element in the geothermal fluid. The results of this analysis are used to determine whether the current use of hot water around Mount Tampomas is appropriate or not. The final section of this paper discusses the key points that can be drawn and potentially applied to other geothermal fields in Indonesia to develop balneology resources based on hydrogeochemical analysis.

3. GEOLOGICAL RESOURCES OF MOUNT TAMPOMAS

3.1 Geological setting

Physiographically, Mount Tampomas is located in the Quaternary Mountain Zone (van Bemmelen 1949). Based on remote sensing analysis using DEM imagery, a circular feature was identified surrounding the current Tampomas Cone. This circular feature is interpreted as the result of the ancient volcanic activity of Old Tampomas (Lumbanbatu, et al. 2005). The presence of this circular feature is also believed to separate the geothermal reservoir compartments beneath Mount Tampomas (Permadi G. B., Herdianita, Amanda, Wibowo, & Putra, 2022). In addition to the circular feature, the lineaments of geological structures in and around Mount Tampomas have NE-SW and NW-SE orientations, which align with the primary stress direction of Java Island, which is N-S.

Based on the geological regional map, the earliest volcanic product, originating from the ancient Mount Sumedang, is represented by volcanic breccia (Qob) found to the south of Mount Tampomas. This was followed by the evolution of Mount Cimalaka, which later underwent a collapse, forming the Cimalaka Caldera (Lumbanbatu, et al. 2005). The younger volcanic products are believed to result from eruptions of Mount Tampomas and its parasitic cones, producing undifferentiated materials (Qyu) scattered around the mountain. Additionally, pumice tuff (Qyt) deposits extend from the south to the west of Mount Tampomas, succeeded by breccia and agglomerate (Qyb) on the lower slopes, and lava (Qyl) shaping the current volcanic cone of Mount Tampomas (Silitonga 1973). The appearance of warm water is located on Quaternary undifferentiated volcanic products (Qyu).

3.2 Geothermal Fluid Characteristics

The geothermal potential area of Mount Tampomas has geothermal manifestations in the form of hot springs and warm water pools. The residents have utilized some of these warm water pools as public bathing places, while others remain as natural discharges. These hot springs and warm water pools are located in the northeastern foothills of Mount Tampomas, namely Ciuyah hot springs (APCU), Cilendre hot springs (APCLD 1,2), Conggeang hot springs (APC 1,2), Cileuncang hot spring (APCLC), Cileungsing (APCL), and there is one warm spring located south of Mount Tampomas in the city of Sumedang, namely Ciseupan warm spring (APCS 1,2). The surface manifestations of Mount Tampomas extend to the north and south, primarily featuring warm springs and pools with temperatures ranging from 34.7°C to 50.7°C.

A Schoeller diagram (Figure 3) describes the pattern of anion and cation contents of 9 geothermal water samples from Mount Tampomas. The diagram also shows a similarity of chemical patterns among the geothermal waters, with comparable levels of Na^+, K+, Ca^{2+}, Mg^{2+}, NH_4^+, Cl^-, and HCO^{3-} ions. However, it indicates that the concentrations of Li^+ and $SO4^{2-}$ in the Ciseupan area (APCS-1 & 2) are lower than in other hot waters. Meanwhile, the highest concentrations of Ca^{2+} and Cl^- are found in the Ciuyah Hot Spring (APCU), which correlates with its physical parameters, having the highest TDS (Total Dissolved Solids) with 19,976 mg/L. In addition, it appears that the NH_4^+ content in the Mount Tampomas geothermal system is indicated to be relatively high.

All physical properties of surface thermal manifestations can be seen in the Table 1. The hydrogeochemical characteristics can be assessed through the analysis of Cl-SO_4-HCO_3 and Na-K-Mg ternary diagrams (Figure 4), which indicates the hydrothermal fluid characteristics based on the primary dissolved elements. Although focused on major anions and cations, these analyses can explain the relationship between the emergence of warm water and the subsurface lithological conditions, which in turn helps identify the occurrence of other trace elements that may appear in specific areas.

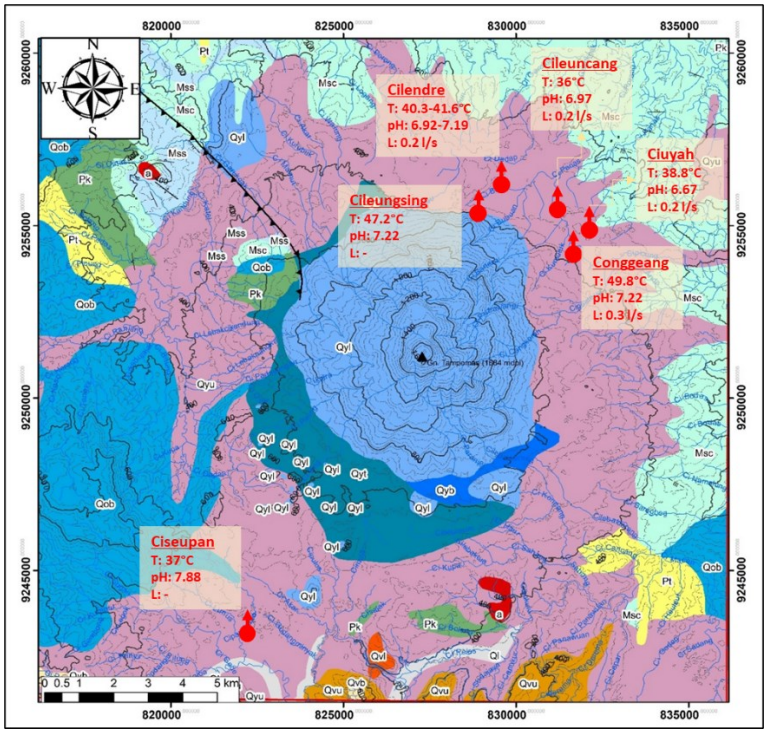

Figure 2: The geological map of Mount Tampomas Geothermal Area and its surface thermal manifestations distribution (modified from Silitonga, 1973).

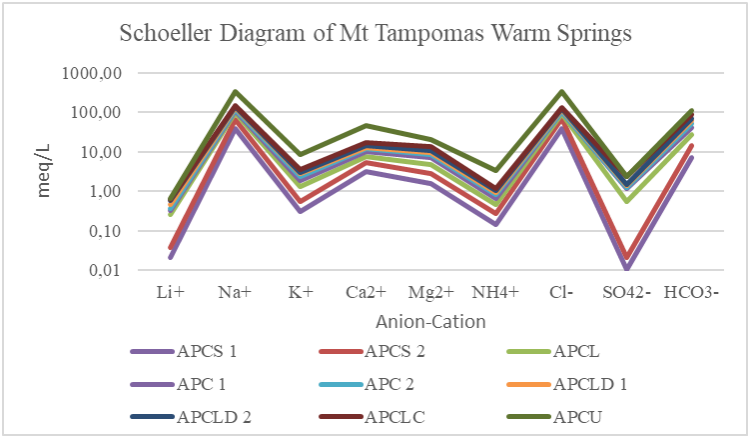

Figure 3: The Schoeller Diagram of chemical constituents within the Mount Tampomas Area.

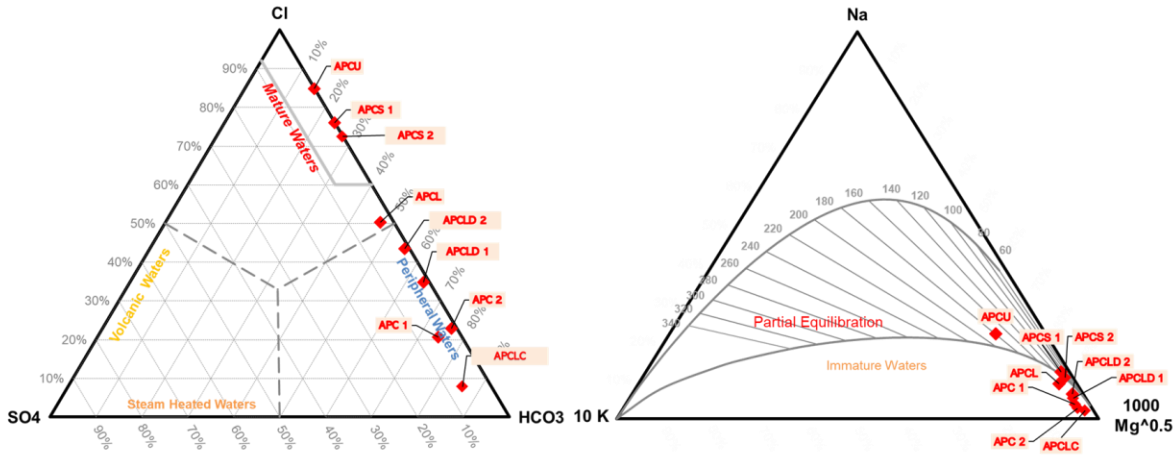

Figure 4: Cl-SO_4-HCO_3 and Na-K-Mg ternary diagrams of warm springs in Mount Tampomas Geothermal Area.

The characteristics of warm water around Mount Tampomas, based on the Cl-SO_4-HCO_3 ternary diagram, can be categorized into three types: chloride water, chloride-bicarbonate water, and bicarbonate water with neutral pH. According to the Na-K-Mg ternary diagram, only Ciuyah Hot Spring (APCU) exhibits partial equilibrium with the rocks of the deep geothermal reservoir, while the other warm waters are characterized as immature water due to mixing with surface water.

Table 1: The physical parameters of warms springs in Mount Tampomas and its surroundings (Geological Agency, 2021).

No	Warm Spring Code	pH	Temp (°C)	EC (μs/cm)	TDS (mg/L)	Remarks
1	APCS 1	7.88	37	4,640	3,560	Carried out from an abandoned public bath pool
2	APCS 2	7.93	34.7	3,610	2,752	The sample was taken from a resident's pump well located not far from APCS 1, with a well depth of approximately 7 meters.
3	APC 1	7.22	49.8	2,350	1,752	Abandoned public warm spring bath, near the main road, residents usually called it Sekarwangi Warm Spring.
4	APC 2	7.06	50.7	1,446	940	A natural warm spring, discharging from a fracture, can be classified as seepage due to its occurrence in the riverbed.
5	APCLD 1	6.92	40.3	1,173	896	A natural warm pool in the middle of the rice field has been utilized as a warm spring bath.
6	APCLD 2	7.19	41.6	1,315	1,028	A natural warm pool in the middle of the rice field, near APCLD 1, has been utilized as a warm spring bath.
7	APCLC	6.97	36	1,277	1,277	A natural warm spring, discharging from a fracture on the riverside, has been utilized as a warm spring bath.
8	APCU	6.67	38.8	2,200	19,976	A natural warm spring that discharges from a fracture has led residents to construct public bathrooms to collect the spring water flow.
9	APCL	7.22	47.2	2,350	1,752	The only hot spring bathing pool that has been commercially utilized.

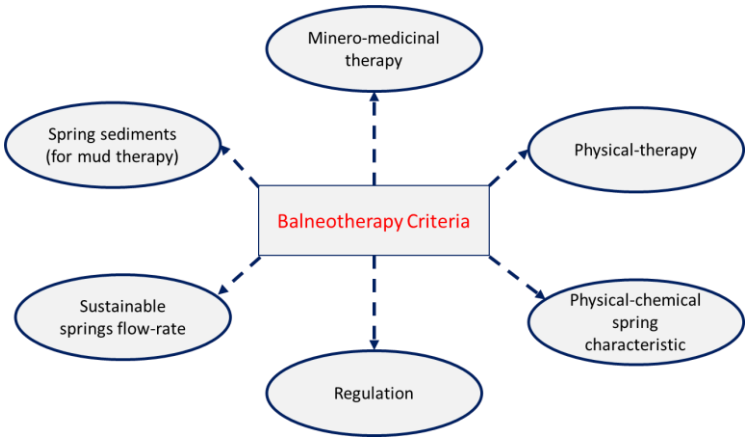

Figure 5: Key criteria in utilizing thermal-water for balneology resource (adopted from Al Dulaymie, et al., 2013).

4. BALNEOLOGY RESOURCE OF MOUNT TAMPOMAS

Through detailed hydrogeochemical analysis, it is inferred that the geothermal manifestations at Mount Tampomas possess characteristics that make them ideal for balneology, the therapeutic use of mineral-rich waters (Sukenik, et al. 1990). The presence of dissolved elements in these geothermal waters aligns with the essential criteria for balneotherapy, which requires water to contain specific minerals to be effective for therapeutic purposes. Such mineral-rich waters are believed to offer various health benefits, including improved circulation, relief from skin conditions, and relaxation of muscles. Given these properties, the geothermal resources at Mount

Tampomas have significant potential for development as a natural source of healing and wellness, attracting interest in both health tourism and local therapeutic use.

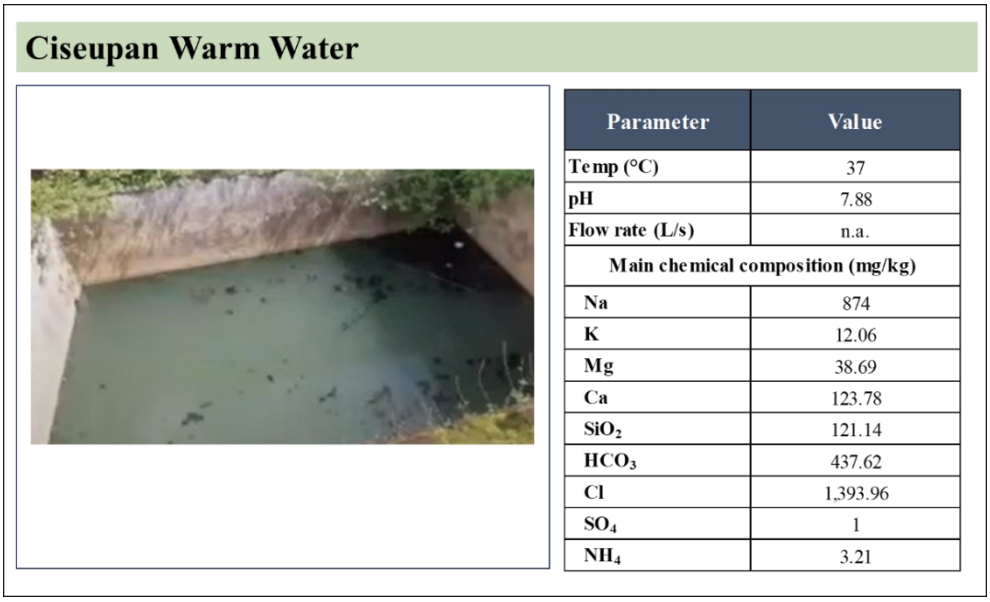
A deeper explanation of the supporting criteria for balneotherapy development goes beyond just the dissolved minerals in hydrothermal fluids. At least six criteria need to be considered when utilizing balneotherapy (Al Dulaymie, et al. 2013), in addition to dissolved minerals for therapy, including the physical benefits it can provide, the benefits arising from the chemical and physical properties of the fluid, dissolved sediments (for areas where mud deposits are present), the sustainability of thermal water flow, and, of course, local regulations that distinguish between warm water and regular groundwater (Figure 5).

A summary of the warm water conditions around Mount Tampomas, including its physical and chemical characteristics, is provided in the following section.

1. Ciseupan Warm Spring

   Ciseupan warm spring is the only warm water that is located to the south of Mt Tampomas, Sumedang City. This warm water source is situated amidst rice fields, near residential areas. Ciseupan warm water was formerly a public hot spring bath, which is no longer in use. Observations and field measurements indicate that this warm water has a temperature of 37°C with a neutral pH of 7.88. The discharge water from this source can no longer be identified, with only a few gas bubbles appearing at the bottom of the pool (Figure 6).

   Not far from the Ciseupan warm pool, there is a community-owned borehole with a depth of approximately 7 meters. The owner of the borehole reported that the water from this borehole is warm, which is supported by field measurements showing a water temperature of 34.7°C with a neutral pH of 7.32. The borehole owner uses this water for daily needs such as bathing, washing, drinking, and cooking. The presence of warm water in this borehole is likely due to a perched aquifer located in this area, which has been influenced by hydrothermal fluids. This is an important observation, as not all thermal waters are suitable for use as drinking water or for cooking.



Parameter	Value
Temp (°C)	37
pH	7.88

2. Conggeang/Sekarwangi Warm Spring

   Conggeang warm water, also known as Sekarwangi warm water, has the highest temperature among the warm water manifestations around Gunung Tampomas, at 49.9°C, with a pH of 7.22 and a measured flow rate of 0.3 l/s. Similar to the Ciseupan warm water pool, the Conggeang warm water pool was initially a public hot spring bath created by the residents to accommodate the flow of warm water from beneath the surface. This warm water pool now appears to be seldom used by the community, with only an outlet channel from the pool being used by some residents for bathing (Figure 6).

Conggeang/Sekarwangi Warm Water

Parameter	Value
Temp (°C)	49.8
pH	7.22
Flow rate (L/s)	0.3
Main chemical composition (mg/kg)	
Na	290.09

SO_4	10
NH_4	2.70

Figure 8: The location of Cilendre warm pool and its physical and chemical parameters (adopted from PSDMBP, 2021).

3. Cilendre Warm Spring

Cilendre warm water is located in a rice field area, with two warm water pools nearby. However, only one pool is used by residents as a public hot spring bath (Figure 8). Field observations indicate that the warm water here appears clearer compared to other thermal waters, which are generally oxidized and contain salt deposits. Field measurements show a water temperature of 40.3°C, a neutral pH of 6.92, and a flow rate of 0.2 l/s.

4. Cileuncang/Bojong Warm Spring

Cileuncang/Bojong warm water is a thermal manifestation that emerges at the riverbank through rock fractures (Figure 9). Residents have constructed an artificial channel to direct the warm water, which is then used as a public hot spring bath. The rocks around this warm water have undergone intensive oxidation. Field measurements indicate that this warm water has a temperature of 36°C, a neutral pH of 6.97, and a flow rate of 0.2 l/s emerging from the rock fractures.

Cileuncang/Bojong Warm Water

Parameter	Value
Temp (°C)	36
pH	6.97
Flow rate (L/s)	0.2
Main chemical composition (mg/kg)	
Na	182.18
K	15.82

Ciuyah Warm Water

Parameter	Value
Temp (°C)	38.8
pH	6.67
Flow rate (L/s)	0.1
Main chemical composition (mg/kg)	
Na	4,108
K	194.46
Mg	162.08
Ca	1,127.28
SiO_2	173.26
HCO_3	1,365.47
Cl	7,688.74
SO_4	10
NH_4	49

Figure 10: The location of the Ciuyah warm pool and its physical and chemical parameters (adopted from PSDMBP, 2021).

5. Ciuyah Warm Spring

As its name suggests, Ciuyah warm water, derived from the word "*uyah*" which means salt, is associated with salt deposits found around its thermal spring discharge (Figure 10). The spring emerges through fracture with a low flow rate of 0.1 l/s. Additionally, this warm water has a temperature of 38.8°C and a pH that is close to neutral at 6.67. Nearby, residents have constructed a public toilet to collect the warm water from this spring, which is used as a public bath.

The uniqueness of this warm spring is that it contains several dissolved elements which based on laboratory analysis, have higher concentrations compared to other thermal waters. These elements include Na, K, Mg, Ca, HCO_3, Cl, and NH_4. The high concentrations of these dissolved elements are suspected to be related to the host rocks of this warm water, which are associated with marine sedimentary rocks that also serve as the reservoir for this thermal water (Iskandar, Demawan, Sianipar, Suryantini, & Notosiswoyo, 2018; Rahayudin, et al., 2018; Permadi G. B., Herdianita, Amanda, Wibowo, & Putra, 2022).

6. Cileungsing Warm Spring

Cileungsing warm water is located in the Buah Dua area and has been commercially used as a public hot spring pool (Figure 11). The natural warm water output at Cileungsing cannot be observed because the residents have constructed artificial pools and channels. This warm water has a temperature of 47.2°C and a pH of 7.22.

Cileungsing Warm Water

Parameter	Value
Temp (°C)	47.2
pH	7.22
Flow rate (L/s)	n.a.
Main chemical composition (mg/kg)	
Na	700.53
K	28.36
Mg	45.83
Ca	92.08

HCO_3	786.20
Cl	848.45
SO_4	50
NH_4	4.16

Figure 11: The location of the Cileungsing warm pool and its physical and chemical parameters (adopted from PSDMBP, 2021).

In addition to considering the dissolved elements, the temperature range of the warm waters at Mount Tampomas, currently used for public baths such as Conggeang/Sekarwangi, Cilendre, Cileungsing, Cileuncang, and Ciuyah, also supports their suitability for public bath. The water temperature, ranging from 36 to 49.8°C, falls within the ideal range for hot spring baths, making it comfortable and beneficial for bathers. This temperature range is not only pleasant for relaxation but is also effective in promoting blood circulation, relieving muscle tension, and providing therapeutic benefits. Therefore, the warm water sources at these locations are well-suited for development as hot spring facilities, offering both recreational and health benefits to visitors.

The therapeutic benefits of spring water primarily stem from the chemical action of minerals, which are absorbed into the skin and bloodstream through osmosis, supporting skin health. The physical impact of spring water is attributed to its temperature, which helps widen the skin's pores, allowing oxygen to flow more easily into the treated tissues. The thermal and mechanical effects of water not only increase blood flow to tissues but also reduce vasoconstriction. The absorption of mineral elements through the skin depends on factors such as skin thickness, blood circulation, exposure method, contact duration, application rate, skin absorption conditions, pressure, temperature, pH, osmotic properties, ion exchange capacity, particle size, chemical form, and environmental conditions. These factors influence processes like osmosis, diffusion, surface tension, cell charge, and metabolism (Morales 2004).

In addition to the presence of dissolved minerals in geothermal water, physical parameters such as temperature and pH can also influence the optimization of hot water utilization for balneotherapy. Temperature variations will affect the recommended duration for the community to soak in the water. The following is an example of a study conducted on the utilization of balneotherapy in warm water around Mount Tampomas. The elements studied include essential elements beneficial to the body, such as Na, K, Mg, and Ca. Additionally, other elements that specifically describe the characteristics of the geothermal system of Mount Tampomas were also examined in this case study, including the main anions Cl, SO_4, HCO_3, and NH_4, which are compounds found in the warm water of Mount Tampomas due to the influence of formation fluids/connate water.

The chemical and physical parameters found in the warm water of Mount Tampomas were compared to the minimum values of Balneological Active Components (BAC) according to Lazzerini and Cardoso da Silva (2020). It can be seen that some of the measured ranges in the Mount Tampomas area are below the minimum BAC values. Further evaluation highlights the high presence of NH_4 in Ciuyah, which may potentially be toxic to the body if used regularly, especially considering that Ciuyah is currently utilized as a water source by local bathhouses. Additionally, it should be noted that while some warm water may be suitable for balneotherapy, it

may not be appropriate for other purposes, such as everyday activities like cooking and washing, which could form the basis for the application of warm water from Ciseupan, as found in local boreholes.

Table 2: The summary of concentration and range of value chemical and physical characteristics of warm water at Mount Tampomas area compared to Balneological Active Components (BAC), red highlights indicate the value is below the minimum BAC (adopted from Lazzerini, et al., 2020; Minister of Health Regulation No.1205/Menkes/Per/X/2004).

Parameter	Unit	BAC	Range of Value	Remarks
Temperature	°C	33	36 - 49.8	**Too hot (>43.3°C)**, thermal water is only for partial body soak: arms, hands, feet, local wraps/compresses. **Hot (37.7-40.5°C), generally** tolerable for most soak therapies: soak duration 15-25 minutes. **Warm water (36.6-37.7°C)**, Slightly above body temperature. Ideal for mineral soak absorption: soak duration 15-30 minutes. **Neutral (32.2-36.6°C)**, Cooling that can be tolerated, used for short-term soaking of less than 5 minutes: for warming reflex.
TDS	mg/kg	444	896-19,976	High TDS contributes give freshness, lightness, softness, malleability, and skin comfort
Flow rate	L/s	1	0.2 - 0.3	The water flow rate affects the sustainability of the appearance of warm water.
pH		8.5	6.67 - 7.88	The pH of the warm water at Mount Tampomas appears to be lower than the BAC (<8.5). Still, in general, all pH levels are categorized as neutral, which has the potential not to cause skin irritation, especially when the therapy is performed over a long period.
Na	mg/kg	725	182.18 - 4108	Sodium in balneotherapy helps maintain Cell renewal and moisturizing
K		20	12.06 - 194.46	Potassium in balneotherapy helps maintain electrolyte balance, improves blood circulation, relieves muscle pain, supports skin health, and aids in detoxification.
Mg		121.6	24.35 - 162.08	Major aqueous dermal absorption rate
Ca		256	43.65 - 1127.28	Sedative, dermatitis, rheumatology
SiO2		25.3	121.14 - 226.40	Anti-inflammatory, adsorption potentiate, sedative, skincare
HCO3		196.6	437.62 - 1365.47	Antioxidant effects, skincare, rheumatology, sedative
Cl		1171	99.75 - 7688.74	Exciting and resolute action, cellular stimulants blood and lymphatic circulation, skincare, rheumatology
SO4		408	20 - 80	Under the BAC
NH4		n.a.	2.70 - 49	There is no specific BAC for NH4 since this content is considered toxic; however, the normal concentration of NH4 in hydrothermal fluids is generally 0.5 mg/kg.

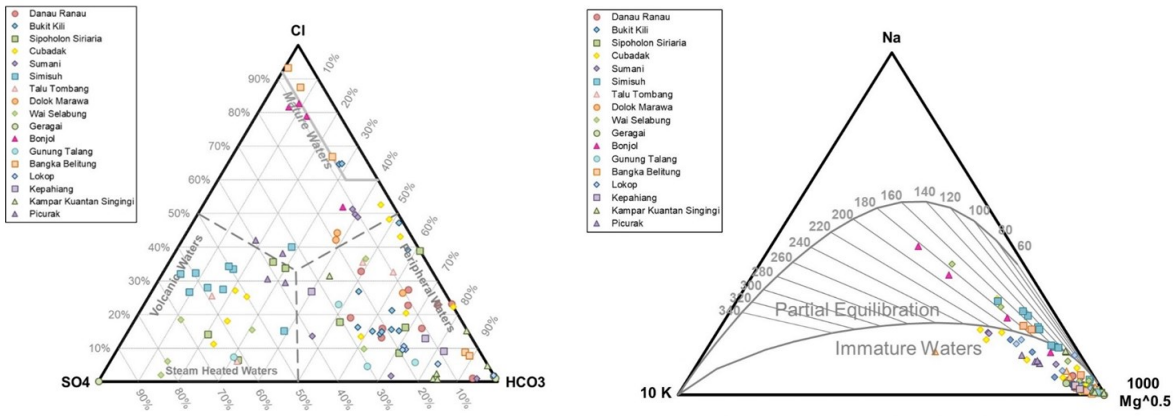

Figure 12: Compilation of Cl-SO_4-HCO_3 and Na-K-Mg ternary diagram of various geothermal systems in Sumatra that may contribute the initial hydrothermal fluid characteristics (Chenchen, et al. 2020).

5. INITIAL ANALYSES OF GEOTHERMAL FLUID GEOCHEMISTRY

For comparison, detailed exploration data from geothermal fields in Indonesia can serve as an initial reference in identifying balneotherapy resources in the country. Figure 12 shows the results of an analysis of major anions and cations in geothermal fluids from fields located on the island of Sumatra. Although this analysis is still quite general, the fluid types and their equilibrium levels can provide an initial indication of whether the thermal fluid

is directly associated with the geothermal reservoir or not. This can also help enhance the initial understanding of the hydrogeochemical system in a geothermal area.

Thermal water associated with geothermal reservoirs will naturally be more effective as a balneology resource compared to thermal water that has undergone near-surface processes, such as steam-heated water or water that has been heavily diluted. This is related to the content of dissolved elements and mineral compounds in thermal water and the level of effectiveness of thermal water absorption by the skin. Nevertheless, the next step is to conduct an in-depth hydrogeochemical analysis to identify the dominant tracers in a given area and their implications for balneotherapy.

6. LOCAL COMMUNITY PERCEPTIONS

The geothermal prospects of Mount Tampomas are well-known, particularly regarding the local community's opposition to any geothermal exploration activities for electricity generation. It has been openly stated that residents reject all surface survey activities and geothermal exploration drilling (Figure 13). However, the local community seems highly enthusiastic about utilizing geothermal energy for public bathing, which is believed to provide health benefits. We believe optimizing geothermal energy should not be limited to electricity generation alone. The direct use of geothermal energy for balneotherapy is a simple example that the community can easily accept.

Figure 13: Several banners from residents around Mount Tampomas expressing opposition to geothermal exploration survey activities.

Moreover, utilizing geothermal energy for balneotherapy can provide an opportunity to increase the local community's knowledge of Mount Tampomas regarding the basic understanding of geothermal systems. In the last survey, several opinions from the community tended to lack understanding of what a geothermal system is. This was evident from several banners stating that geothermal drilling activities could trigger the release of chemical elements from beneath the earth to the surface. In fact, without realizing it, these geothermal chemical elements can naturally dissolve in hot water and are not entirely harmful to humans. Thus, this balneotherapy study can help bridge the knowledge gap in the local community.

7. CONCLUSION AND PATH FORWARDS

Here is the conclusion of the lessons learned from the utilization of balneotherapy in the Mt Tampomas Geothermal Area:

- Balneotherapy is an alternative direct-use application that can be implemented in the Mt Tampomas geothermal area, which faces community rejection issues during the exploration phase.
- Hydrogeochemical analysis can bridge the characteristics and uniqueness of the fluids in a particular geothermal field, as the dissolved chemical content in hydrothermal fluids may offer benefits or even be toxic at certain levels.
- In addition to dissolved chemical elements, other physical parameters such as manifestation temperature, pH, and flow rate are also considered in optimizing balneotherapy.

- A key lesson learned from the balneology resources in Mount Tampomas, particularly in the Ciseupan area, is that not all warm water suitable for balneotherapy can be used for other purposes. This highlights the need for careful evaluation of water properties to ensure safe and appropriate use, considering that water fit for therapeutic purposes may not always meet the standards required for daily activities such as cooking and washing.

In addition to technical aspects, the utilization and study of balneotherapy in Indonesia can specifically involve several key stakeholders necessary to develop balneotherapy systematically. The following is a summary of the stakeholders that should at least play a role in the development of balneotherapy in Indonesia. Naturally, this must also be accompanied by the development of regulations that will serve as a reference for future balneotherapy development in the country.

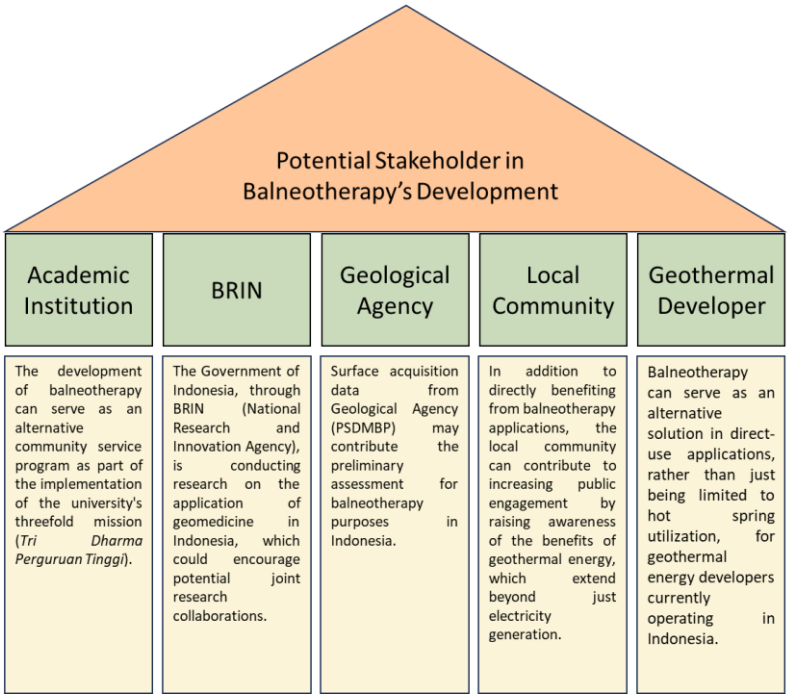

Figure 14: Potential stakeholder for developing balneotherapy as a geothermal direct-use utilization in Indonesia.

Keywords: Geothermal Energy Investment, Off-Grid Power Solutions, Renewable Energy Economics, Mining Industry Electrification, Regulatory Challenges in Geothermal

ABSTRACT

Indonesia is recognized as the world's second-largest producer of geothermal energy, yet it has exploited only approximately 10% of its estimated 23.9 GW capacity, utilizing merely 2,418 MW. The Indonesian government has ambitious plans to increase geothermal power generation to 5,799 MW by 2030, which necessitates an acceleration in geothermal development. However, the acceleration of these investments is hindered by the low bankability of geothermal projects, primarily due to insufficient returns for investors and limited debt repayment capacities for lenders. This is exacerbated by high initial investments and unfavorable tariffs influenced by the unattractive regulated ceiling tariffs and substantial bargaining power of on-grid buyers.

This study aims to evaluate the economic viability of off-grid geothermal sales through off-grid sales to industry/mining compared to conventional on-grid electricity sales. The study also identifies potential challenges and opportunity for off-grid geothermal Utilization in Indonesia. The research uses the Political, Economic, Social, Technological, Environmental, and Legal (PESTEL) framework to analyze the general external condition of the geothermal business in Indonesia. The project finance data sourced from published reports and publication is used to perform capital budgeting and scenario analysis to determine which business scheme provides better bankability. The project bankability assessment is performed from both the investor's and lender's perspectives, focusing on returns (Net Present Value-Internal Rate of Return) and debt repayment ability (Debt Service Coverage Ratio).

The result indicates off-grid geothermal sales have promising bankability rather than the conventional on grid electricity sales since have higher return and stronger repayment ability. It is supported by the opportunity from mining industry appetite to enhance business sustainability and increasing demand of green electricity. The key challenges derived from legal perspective since Indonesia does not establish clear regulation related to off grid geothermal utilization. This research also suggest government to develop clear regulation framework for geothermal off-grid utilization in Indonesia.

1. INTRODUCTION

The geothermal development in Indonesia has started from colonized era with commercial utilization remarked through Kamojang Geothermal Power Plant (30MW) in 1983 (Darma, Imani, Shidqi, Riyanto, & Daud, Country Update: The Fast Growth of Geothermal Energy Development in Indonesia, 2021; Mansoer & Idral, 2015). Nowadays, Indonesia is top two geothermal country in the world with 2.417 MW installed capacity from approximately 23 GW total potential. It means that Indonesia only utilized around 10% of total potential with average additional capacity around 60 MW per annum (ThinkGeo, 2024). There are 46 geothermal power plants developed by State-Owned Enterprises (SOE) and Independent Power Producer (IPP) in 17 geothermal working areas (Pambudi, 2023).

Government of Indonesia has plan to utilize geothermal as baseload to replace coal power plant and set the target of utilization to reach 5.799 MW in 2030 (Fadhillah, Tjendarsa, Damayanti, Purba, & Adityatama, 2024). The government target emphasizes the significant increase in average of additional installed capacity toward 488 MW per annum from 2024 to 2030. This bold target needs to be achieved by catalyzing geothermal investment though better project attractiveness, including from project economic perspective. Figure 1 shows the historical and target for geothermal power utilization based on PLN (2021), EBTKE (2023) and ThinkGeo (2024).

1.1 Opportunity and Challenges of Geothermal Business

Government of Indonesia emphasizes geothermal as the second largest power generation from renewable energy by 2025. It targeted to support 16.9% of renewable energy power generation, equal to 7.56% of the total national electricity demand, with the increasing utilization over the year (PLN, 2021). The utilization of geothermal as

green energy is important in Indonesia's efforts to achieve 23% renewable energy by 2025 and another additional 21% of renewable power generation by 2030. The regulatory indicator for renewable energy (RISE) index by the world bank (2018) placed Indonesia in high-rank performance related to the renewable energy legal framework. The government of Indonesia has already set clear energy roadmap under energy law to support the renewable energy effort, including the fiscal incentives, government drilling programs, and risk mitigation programs (ESMAP, 2016).

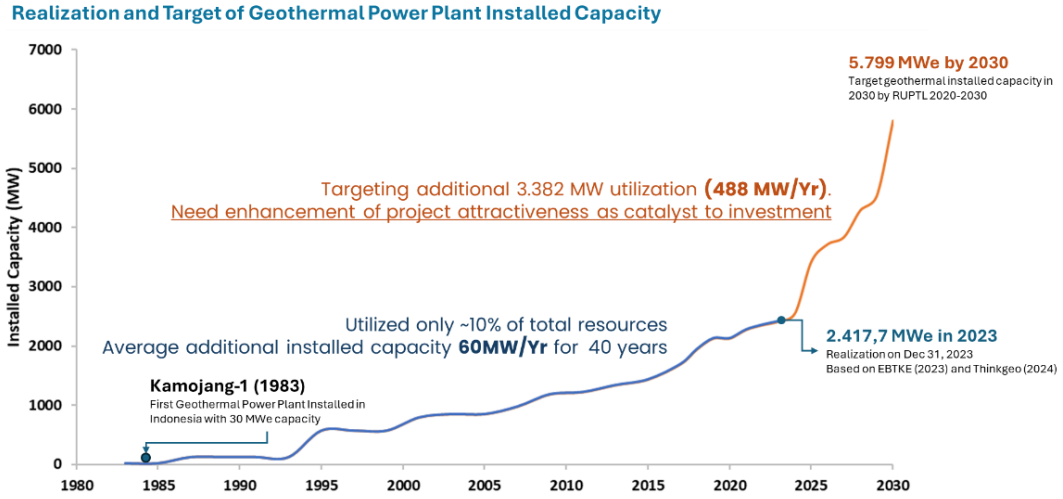

Figure 1: Indonesia geothermal power plant installed capacity and target for 2023 based on EBTKE (2023) and Thinkgeo (2024).

Research by Geothermex (2010) and Castlerock (2010) emphasizing that the main barrier to geothermal development in Indonesia lies in the significant risk involved during extensive investments. Indonesia's geothermal sector possesses significant potential, yet it remains unattractive to investors due to the high risks and low returns involved. Geothermal projects often face substantial hurdles in achieving adequate returns and satisfactory repayment capabilities due to a mismatch between regulated ceiling tariffs and project costs and risk profiles. Many projects fail to progress to the production phase because of unfavourable economic conditions, challenging resource characteristics, and social issues, all of which are influenced by political, economic, social, and technical factors.

Geothermal electricity sales face high power of the buyer since it only allowed by regulation to sell for Perusahaan Listrik Negara (PLN) as single buyer through power purchasing agreement (PPA). The high power of buyer could impact the cashflow of the business since buyer has stronger position put lower price. It regulates the sales contract for 30 years with tariff mechanisms per presidential regulation 112/2022. The PLN has the right to negotiate the geothermal tariff with the developer in business to business (B to B) approach with their primary objective to obtain efficient as low as possible electricity tariff which may not be attractive for investor. Table 1 shows the key challenges of geothermal project by ESMAP (2021).

Table 1: The general challenges of geothermal project.

Aspect	Challenges
Political - Legal	• Geothermal projects can be influenced by political instability, changes in government, or shifts in energy policies. Political instability can lead to delays in decision-making and project execution, affecting the project's financial performance and overall viability. • Uncertainties due to changes in government policies, regulations, or permitting processes. Delays in obtaining necessary approvals or unexpected changes in regulatory requirements can lead to project disruptions, increased costs, and uncertainty in project timelines
Economic	• Potential discrepancy between the expected revenue of the project and the actual realization, not necessarily due to lower production, but rather the possibility that the developer may not receive the payments for the production as initially anticipated. • One of the primary risks is cost increases, which can occur due to factors such as inflation, fluctuations in material prices, or unforeseen expenses during construction and operation. These cost overruns can strain the project's budget and affect its economic feasibility. Furthermore, changes in financing conditions, including fluctuations in interest rates or currency exchange rates, can expose the project to financial volatility. Higher interest rates

Aspect	Challenges
	can increase borrowing costs, while currency changes may affect debt repayment obligations and project revenue.
Social-Environmental	• Social environment risks in geothermal projects include community opposition, land rights and displacement issues, environmental impacts, concerns about cultural heritage, health and safety risks, and challenges in equitable benefit sharing.
Technical	• The risk that the production drilling campaign may fail to achieve the required capacity or do so with cost overruns. This pertains to the possibility of encountering challenges during the drilling process that could impede reaching the intended capacity or result in unforeseen expenses. • Risk of resource depletion due to exploitation, making it unsustainable for the planned duration. In this scenario, the geothermal resource may not perform as initially estimated, leading to difficulties in maintaining production at the power plant in accordance with the intended capacity. • Risks related to technical issues that may arise during drilling, plant construction, or plant operation. The challenges may lead to adverse impacts, including escalated costs, delays in project timelines, or revenue losses due to reduced energy generation. • Risks related to natural hazards such as earthquakes, floods, and volcanoes, which could impact the project's operations and infrastructure. Additionally, security risks in the area may pose challenges and uncertainties that need to be considered. • Risks include delays, management issues, inadequate budgeting, and procurement challenges. Proactive strategies and effective planning are crucial to address these risks and achieve project objectives.

1.2 Problem Statement

The Alpha project, a hypothetical geothermal project in Indonesia, encounters difficulties in providing acceptable return to shareholder and securing external funding due to inadequate cash flow to meet liquidity requirements. This situation presents significant barrier to project advancement, given the high upfront costs required for resource confirmation and production, alongside the need for commercial financing for development. Furthermore, the project struggles with negotiating tariffs and securing Power Purchase Agreement (PPA) a critical requirement for obtaining project financing from lenders, with single state off-taker.

Project owner is considering the option of selling steam directly to a nearby mining operator, which also demand this supply to support electricity for its operations. The project is evaluating two potential sales scenarios: selling electricity to the state off-taker (Business as Usual) or direct sales to a nearby mining operator (off-grid sales). To determine the most advantageous scenario for the project, shareholders, and potential external financiers, the project owner needs a comprehensive economic analysis through this study.

1.3 Research Question and Objective

The objective of this paper is to provide project economic analysis with recommendations to geothermal project in determining the sales scenario to provide better return and repayment ability. The research questions are:

1. How is the project economic comparison between Business as Usual and off grid sales? Which scenario provides better return and repayment ability?
2. If the off-grid scheme is more attractive, where are the potential area in Indonesia to apply similar scheme?

2. GEOTHERMAL BUSINESS OVERVIEW

2.1 Geothermal Business Model: On Grid versus Off Grid

In the geothermal industry, the primary product is steam that used for electricity generation. This utilization represents the main revenue stream for geothermal projects in Indonesia. Under typical business conditions, the generated steam or electricity is purchased by Perusahaan Listrik Negara (PLN), the state-owned electricity company, which acts as the sole buyer. PLN's position as the single buyer serves it significant power in the market, particularly in determining tariffs, that often supports its advantage (Fadhillah, 2023). Subsequently, PLN also transmits and distributes electricity to consumers across various sectors, including industrial, commercial, and residential users (Brilian, et al., 2024). This arrangement is known as the on-grid model.

The off-grid utilization concept aims to bypass PLN and sell electricity or steam directly to industrial consumers. This approach is intended to offer more competitive tariffs and streamline the negotiation process. Developers would negotiate the Power Purchase Agreement (PPA) or steam sales contract directly with potential buyers

following the Notification of Resource Confirmation (NORC), which provides option for developer to choose the buyer. In an electricity sales scheme, the project stages remain similar to the business-as-usual model, including survey, exploration drilling, development drilling, and the construction of a Steam Above Ground System (SAGS) and a power plant. In contrast, under a steam sales contract, the developer can avoid the expense and effort of constructing the SAGS and power plant, as these would be prepared by the off taker. Figure 2 illustrates the business model of on-grid and off-grid, while Table 2 summarizes the difference between both schemes.

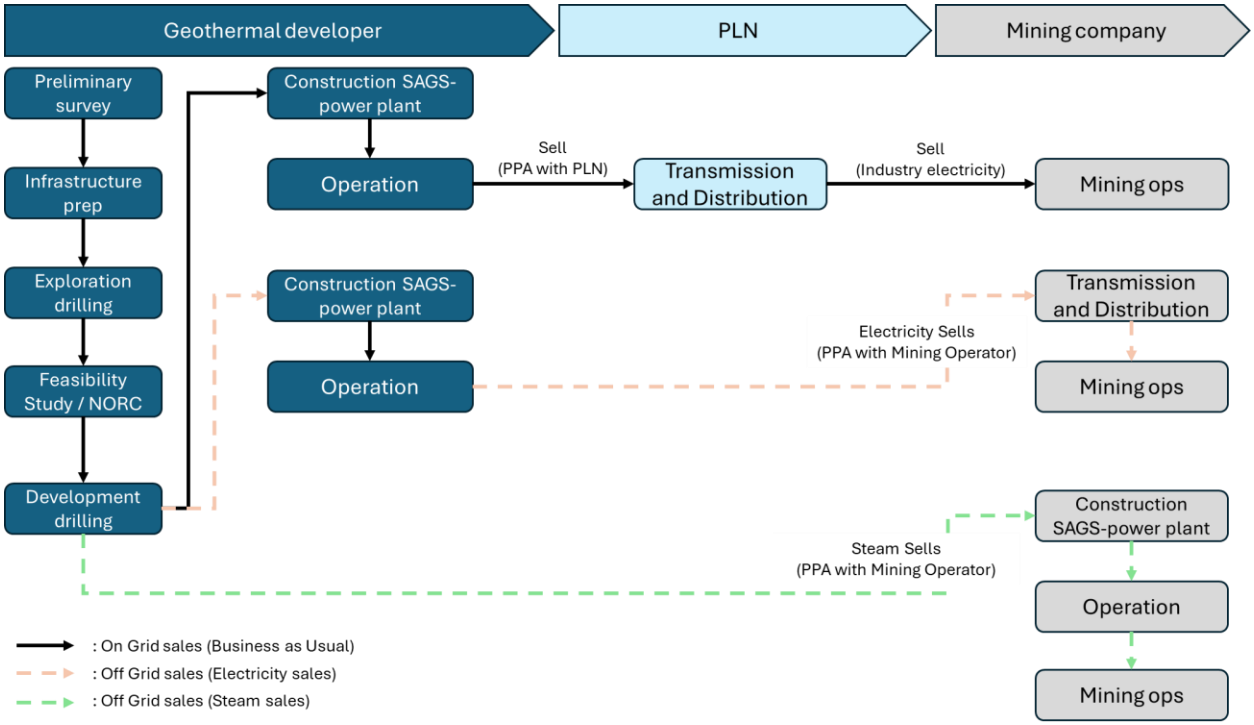

Figure 2: The differences between conventional geothermal power generation and geothermal captive use business models for the industrial sector.

Table 2: The differences between On Grid and Off Grid.

Parameter	On grid (electricity sales)	Off grid (electricity/steam sales)
Buyer	PLN, (single offtaker, the amount will be dependent to PLN roadmap)	Private or SOE, (potential for multiple buyers based on industry demand and resource condition)
Developer's power for negotiation	Very low, developer face no option of buyer.	Moderate, Developer may have several potential buyer(s)
Negotiation process	Prolong negotiation since PLN also encounter many projects and need calculation related to state subsidy for electricity.	Expected for more efficient process since the buyer usually need the power in certain date.

2.2 Indonesia Regulated Tariff Scheme

Indonesia's geothermal tariff framework uses ceiling with staging system, determined by the power plant's location and capacity. This method is specified in Presidential Regulation 112/2022, which updates the earlier ceiling tariff structure. The staging system splits the operational lifespan of a geothermal power plant into two phases: Stage 1 (years 1 to 10) and Stage 2 (years 11 and beyond). Each phase has a separate ceiling for the base tariff that developers can negotiate with PLN (GoI, 2022). Additionally, the location factor serves as a multiplier index for the base tariff during Stage 1. This adjustment accounts for the variation in development costs resulting from differing infrastructure conditions across regions (MEMR, 2022b). Figure 3 shows the distribution of base tariff and location factor. The calculation of the applied base tariff as below.

$$Tariff\ stage\ 1 = agreed\ tariff\ x\ location\ factor$$

$$Tariff\ stage\ 2 = agreed\ tariff$$

Geothermal Power Plant – electricity price

Capacity (MW)	Ceiling Price (HPT)							
	s.d 10 MW		>10 MW s.d. 50 MW		>50 MW s.d 100MW		>100 MW	
	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30	Stg thn 1-10	Stg thn 11-30
Staging Price (cent $/kWh)	9,76 x F	8,30	9,41 x F	8,00	8,64 x F	7,35	7,65 x F	6,50
Levelized Price (cent $/kWh)	9,25		8,92		8,19		7,25	

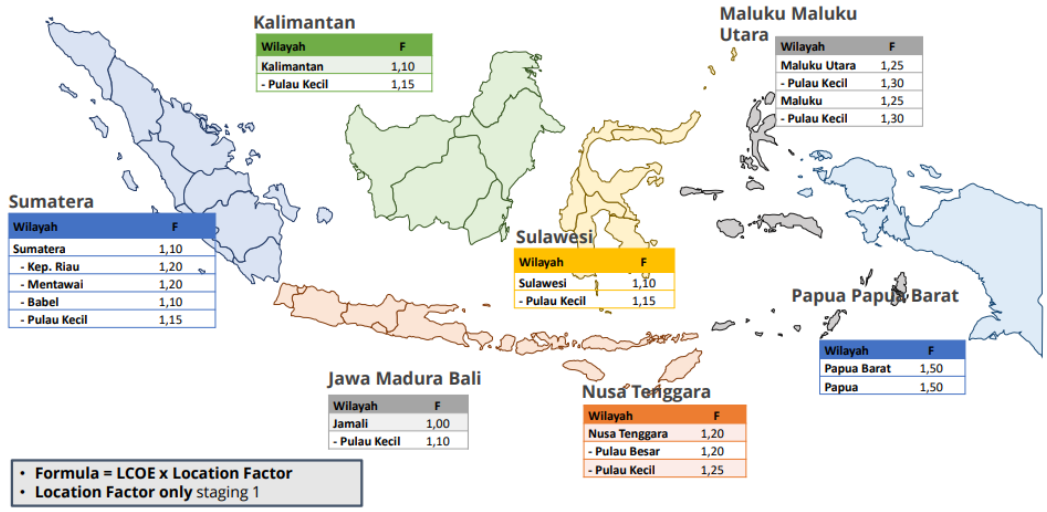

Figure 3: The base tariff and location factor of geothermal tariff under presidential regulation 112/2022.

ADB (2014) explained that Indonesia's geothermal tariff adopts an escalation approach over the years, utilizing a partial percentage of the tariff (α) to adjust the tariff values. The escalation factor used for this adjustment is based on the United States Producer Price Index (US PPI), as the contracts are denominated in USD. The calculation is as follows:

$$P(t) = [(1 - \alpha)P(0)] + [\alpha P(0)USPPI(t)/USPPI(0)]$$

where

P(t) = Tariff in year t, in US¢/kWh

P(0) = (base) tariff at COD = Tariff bid at time of tender, in year (0)

USPPI(t) = United States Producer Price Index for year (t)

USPPI(0) = United States Producer Price Index for year (0)

α = Coefficient (determined by ad-hoc discussion with range 0.25-0.4)

3. METHODOLOGY

The study gathers secondary data through an extensive literature review, concentrating on the financial parameters of geothermal projects within the on-grid scheme. This involves examining previous studies, reports, and relevant regulations to understand the cost structures, revenue models, and financial performance of on-grid geothermal projects. Key financial parameters analyzed include capital expenditure (CAPEX), operational and maintenance (O&M) costs, tariffs, and projected revenues.

To evaluate the economic outcomes of both on-grid and off-grid scenarios, the author develops and simulates a comprehensive financial model. This model incorporates various economic parameters such as initial investment costs, ongoing operational expenses, expected revenues, discount rates, and potential financing structures. The simulation helps determine key financial metrics like net present value (NPV), internal rate of return (IRR), and Debt Service Coverage Ratio (DSCR), providing a clear picture of the project's economic feasibility under different scenarios.

Furthermore, the author conducts a literature review to identify the potential challenges associated with off-grid utilization. This includes examining issues such as regulatory barriers, technical challenges, market demand uncertainties, and social acceptance. The review also explores potential geographic areas where off-grid geothermal projects could be most viable, considering factors like proximity to industrial users, resource availability, and infrastructure conditions.

By combining data from literature reviews, expert consultations, and financial simulations, the study aims to provide a thorough analysis of the economic feasibility and potential challenges of both on-grid and off-grid geothermal project utilization in Indonesia.

4. DISCUSSION

4.1 Project Economic Analysis

4.1.1 On Grid Scenario

The cashflow is discounted to determine the project feasibility through NPV and IRR. The applied discount rate for project cashflow is equal to WACC (7.12%), while the equity cashflow use discount rate on cost of equity (11%). Although cumulative cashflow shows positive condition, the result of Alpha project economic calculations shows infeasible condition for equity. The NPV for project and equity cashflow shows negative condition, where NPV project equals -14.12 MUSD and NPV equity equals -41.22 MUSD. The IRR calculation for project and equity falls below the discount rate. The IRR project is 6.52%, while the IRR equity is 6.39%. The result of NPV and IRR indicates the project does not provide fair return to the equity.

The calculation of Debt Service Coverage Ratio (DSCR) reveals that the XYZ project fails to meet the lender's requirements regarding the minimum DSCR. The lender stipulates that the minimum DSCR should not fall below 1.2 throughout the project's duration. However, the XYZ project's minimum DSCR is recorded at 1.07, indicating a deficiency in meeting the lender's specified threshold. The low DSCR of 1.07 signals to the lender that the project may struggle to generate sufficient cash flow to service its debt obligations. As a result, the lender may view the project as higher risk and may be hesitant to extend the requested funding or impose more stringent loan conditions to mitigate potential risks.

4.1.2 Off Grid Scenario

The cash flow analysis for the off-grid utilization of geothermal energy to support mining operations in Indonesia indicates promising returns with improved repayment capabilities. The enhanced project cash flow stems from achieving more favorable tariffs in agreements with mining operators. The determination of these tariffs has undergone a more efficient process, accelerating the project's operational start date. Consequently, this efficiency boost positively impacts the project's Net Present Value (NPV) and Internal Rate of Return (IRR).

The improved tariff arrangements not only expedite the project's operational timeline but also contribute to a stronger financial outlook. Higher tariffs result in increased revenue, which, in turn, enhances the project's cash flow stability. This financial improvement significantly bolsters the Debt Service Coverage Ratio (DSCR), reflecting the project's strengthened ability to meet its debt obligations.

4.2 Geothermal Energy Utilization to Support Mining Electricity

High-temperature geothermal systems are often linked to volcanism and tectonic activity, with many high-enthalpy geothermal resources also associated with high concentrations of hydrothermal alteration minerals such as gold and copper, this is due to the tendency of precious metals to precipitate and deposit as a result of the boiling and mixing of deep geothermal fluids. When managed effectively, this condition can benefit mining operations, as geothermal energy can provide a sustainable energy source that aligns with the goals of many mining companies (Patsa, Zyl, Zarrouk, & Arianpoo, 2015).

Mining industries typically prefer gas turbines or diesel generators for captive energy use due to their low upfront costs, compact equipment, quick installation, and short ramp-up periods (IRENA, 2019). However, these energy sources pose significant operational challenges, such as expensive fuel requirements and an insecure fuel supply chain, particularly in rural areas or remote islands. Additionally, the use of fossil fuels creates high greenhouse gas (GHG) emissions which does not align with global target and management direction towards sustainable mining operation.

The presence of geothermal potential near industrial sites presents a promising option for a relatively inexpensive and clean energy source for captive use, as shown in Table 2 and Figure 4. The levelized cost of electricity (LCOE) for geothermal energy is significantly lower than that of diesel generators and is comparable to that of gas turbines. Additionally, geothermal energy produces negligible greenhouse gas (GHG) emissions compared to diesel and natural gas.

The alignment of geothermal energy with sustainable mining operations is particularly noteworthy. Sustainable mining practices prioritize reducing environmental impact and minimizing carbon footprints, goals that geothermal energy supports effectively. By providing a stable and reliable energy source with low operational costs, geothermal energy can help mining companies achieve their sustainability targets while ensuring energy security.

Moreover, the LCOE values in Table 2 and Figure 4 do not account for externalities such as carbon taxes on fossil fuel power generation. If these externalities were included, the LCOE for geothermal power plants (GPP) would likely be even more favorable. This further enhances the appeal of geothermal energy for mining operations, as it not only offers cost savings but also aligns with regulatory trends toward carbon pricing and environmental accountability. It supports the industry's move toward greener practices by significantly lowering GHG emissions and providing a more stable and sustainable energy source. This alignment with sustainable mining goals makes geothermal energy a strategic choice for companies looking to enhance their environmental stewardship while maintaining economic viability.

Brillian (2024) compares various energy source that utilized in mining operation to geothermal and potential area of mining that adjacent to geothermal in Indonesia. Geothermal energy offers several advantages, making it an attractive option for sustainable industrial operations, particularly in sectors like mining. One of its primary benefits is the low levelized cost of electricity (LCOE), which ranges from 3.6 to 13.4 USD¢/kWh, significantly lower than diesel generators and comparable to gas turbines. Additionally, geothermal energy boasts a high-capacity factor of 80-95%, ensuring a reliable and consistent energy supply. It also produces minimal greenhouse gas emissions (0.02-0.24 kg CO2e/kWh), making it a much cleaner option compared to diesel and gas turbines. Unlike these fossil fuel-based energy sources, geothermal energy requires no fuel, eliminating supply chain issues and reducing operational costs. Furthermore, geothermal projects are exempt from carbon taxes, providing a financial advantage.

However, geothermal energy also presents several challenges. The initial capital expenditure is high, ranging from $4-6 million per MW, significantly more than the $0.5-0.8 million per MW for diesel generators and $0.8-0.9 million per MW for gas turbines. Geothermal projects also require substantial land (5,000-20,000 m²/MW), which can be a limiting factor in densely populated or land-scarce areas. The installation duration for geothermal projects is long, typically taking 5-7 years to complete, compared to less than a year for diesel generators and 2-4 years for gas turbines. Additionally, geothermal plants have a moderate ramp-up time of 10-20 minutes, longer than the less than 1-minute ramp-up time for diesel generators, though similar to gas turbines.

4.3 Challenges of Geothermal Off Grid Utilization

The off-grid or captive use of geothermal energy to support mining operations in Indonesia presents a unique set of challenges that must be addressed to realize its full potential. One of the primary challenges is the high cost associated with geothermal as source of energy, especially compared to gas plants. For mining operations, this can be particularly daunting, as they must balance these costs against the economic benefits of using a reliable and sustainable energy source.

Regulatory and policy frameworks also pose challenges to the off-grid use of geothermal energy for mining. In Indonesia, the regulatory environment for geothermal development is complex, with multiple permits and approvals required from various government agencies. This can lead to delays and increased costs for mining companies seeking to adopt geothermal energy. Furthermore, the current regulatory framework may not adequately address the specific needs and circumstances of off-grid geothermal projects, particularly those that serve captive users like mining operations. There is a need for more streamlined and supportive policies that facilitate the development of off-grid geothermal projects.

The regulatory and policy landscape further complicates the adoption of off-grid geothermal energy for mining in Indonesia. The regulatory framework governing geothermal development is multifaceted, involving numerous permits and approvals from various governmental agencies. This complexity can result in delays and increased costs for mining companies pursuing geothermal energy solutions. Furthermore, the current regulatory framework may not fully address the unique requirements of off-grid geothermal projects, particularly those catering to captive users like mining operations. There is a pressing need for more streamlined and supportive policies to facilitate the development of off-grid geothermal initiatives.

Logistical and operational challenges also play a critical role. Mining operations are frequently situated in remote, difficult-to-access areas, complicating the transportation and installation of geothermal equipment. The absence of existing infrastructure, such as roads and power lines, exacerbates these challenges, making it difficult to establish and maintain geothermal facilities. Moreover, the intermittent nature of mining operations, which often experience fluctuating energy demands, necessitates flexible and adaptive geothermal energy solutions capable of efficiently meeting varying load requirements.

A significant concern is the financial risk related to the purchasing power of the off-taker, particularly when the off-taker is a private entity such as a mining operator. The reliance on a single private off-taker introduces a degree of financial uncertainty. The purchasing power of the mining operator can be influenced by various factors, including fluctuations in commodity prices, operational challenges, and overall market conditions. Should the

mining operator encounter financial difficulties, this could adversely affect their ability to honor long-term power purchase agreements, thereby impacting the project's revenue stream and financial stability.

5. CONCLUSION

The off-grid utilization of geothermal shows promising potential since it may provide better tariff for geothermal developer with fair negotiation process. The scheme needs further preparation to tackle various challenges and optimize its potential in Indonesia. The regulator, business owners, mining operators, and financers is recommended to held through discussions to formulate excellence scheme for off grid geothermal utilization.

Keywords: circular economy, environmental conservation, geothermal resource management, sustainable mining, valuable mineral recovery

ABSTRACT

Geothermal energy, a significant form of renewable energy, has conventionally been employed for generating electricity and heating purposes. This study presents a novel approach to geothermal use by investigating the comprehensive extraction and circular economy of essential elements from geothermal brine. In this study, we introduce novel methodologies that enable the retrieval of valuable minerals, such as lithium and silica, from geothermal brine. Consequently, this process effectively converts geothermal brine into a reservoir of valuable resources. This method not only enhances the exploitation of geothermal sites in a more diversified manner but also corresponds with the fundamental principles of the circular economy. The circular economy model effectively reduces waste and enhances resource efficiency by implementing sustainable extraction methods and recycling procedures. This study thoroughly examines the extraction procedures, assessing their viability, effectiveness, and ecological consequences. Moreover, adopting this comprehensive methodology mitigates the environmental impact by diminishing the reliance on conventional mining practices and fostering conscientious resource stewardship. This study makes a valuable contribution to sustainable practices by proposing a change in geothermal operations from single-purpose energy production to multifunctional resource recovery. By doing so, it aims to enhance the long-term viability of geothermal resources. This study represents a significant advancement in reevaluating the function of geothermal energy within the framework of a circular economy, with a focus on fostering environmental conservation, stimulating economic development, and ensuring the sustainable utilization of resources.

1. INTRODUCTION

Geothermal energy has long been recognized as a valuable renewable source, mainly used for electricity generation and direct heating. Historically, the primary focus has been on using thermal energy from geothermal reservoirs to generate electricity. However, the geothermal business is on the verge of a paradigm revolution fueled by the demand for more sustainable and diverse resource utilization strategies. Geothermal brine, a byproduct of geothermal energy extraction, comprises a diverse range of dissolved minerals and elements, including lithium, silica, and other vital compounds (Kusumastuti et al., 2018; Qurrahman et al., 2021). Historically, these ingredients have been neglected, with brine frequently being re-injected into the reservoir or disposed of without fully realizing its potential. This mistake represents a missed opportunity to pursue a more sustainable and efficient resource management approach.

In light of the expanding global need for essential minerals such as lithium for electric car batteries and silica for various industrial applications, extracting these elements from geothermal brine appears to be a feasible alternative (Goldberg et al., 2023). This strategy not only complies with the ideas of the circular economy but also reduces the environmental impact of typical mining practices. The geothermal business can transition from a model of

single-purpose energy generation to a multifunctional resource recovery paradigm by using geothermal brine as a source of valuable minerals (Kölbel et al., 2023). The circular economy paradigm strongly emphasizes encouraging sustainable activities, improving resource efficiency, and cutting waste. By incorporating these ideas into geothermal operations, more sustainable and eco-friendly procedures may be developed. These principles are realized by the complete extraction of valuable elements from geothermal brine, which reduces the environmental impact of energy production and converts waste into resources.

One significant challenge in utilizing geothermal brine is silica deposition, which can clog pipes and equipment. This issue necessitates effectively managing and using silica to prevent operational disruptions (Setiawan et al., 2019). The potential to convert this byproduct into a valuable resource further underscores the importance of comprehensive mineral extraction from geothermal brine. In addition to silica, other valuable minerals such as lithium can be harnessed, adding economic value and promoting resource efficiency within the geothermal industry.

This study investigates novel approaches to extracting silica, lithium, and other necessary components from geothermal brine. It evaluates various extraction processes' effects on the environment, economy, and technical viability. The results are intended to offer a solid basis for reframing the function of geothermal energy in a circular economy, encouraging environmental conservation, and advancing sustainable economic growth. The long-term sustainability and viability of geothermal resources are enhanced by this research, which refocuses the emphasis from energy generation to resource recovery. It emphasizes how crucial it is for the geothermal business to include cutting-edge extraction methods and circular economy ideas to pave the path for a more resource-efficient and sustainable future.

2. GEOTHERMAL BRINE

Geothermal brine refers to a high-temperature solution of salts that flows through solid rock and becomes enriched with solutes from the surrounding rock (Kabay et al., 2018). A multitude of chemical constituents are dissolved within geothermal brines in the various strata of the Earth. Lithium is an extractable constituent found in geothermal brines. Seawater is the primary source of lithium, but the amount of lithium found in seawater is relatively tiny, specifically 0.1-0.2 mg/dm^3. Geothermal brine technology offers significant potential, with concentrations ranging from 10 to 500 mg/dm^3 (Siekierka, Tomaszewska, and Bryjak, 2018).

Indonesia has numerous geothermal brine sources, primarily located in the region stretching from the island of Sumatra to the islands of Nusa Tenggara. There are a minimum of 62 geothermal sites situated on Java Island that can be utilized for their thermal resources. These fields are distributed across the entire island (Setijadji, 2010). Geothermal regions can be classified into fault-hosted and volcano-hosted geothermal systems based on their underlying geology. Seven geothermal developments are located in volcanoes, and out of these, five can generate power (Purnomo and Pichler, 2014). Geothermal faults that are hosted are often not well-developed and are hardly investigated because the energy produced is negligible.

As previously stated, geothermal systems in Java are categorized into volcanic and fault hosts. Out of the twenty-five researched geothermal systems, only eight are classified as fault-hosted, while the rest are volcano-hosted. The eight fault-hosted systems are Pacitan, Maribaya, Batu Kapur, Pakenjeng, Cilayu, Cikundul, Cisolok, and Parangtritis. Segaran, Arjuna-Welirang Volcano, Mount Lawu, Mount Ungaran, Dukuh Temple, Dieng, Kalianget, Slamet Volcano, Ciawi, Sumur Village, Tampomas, Cipanas, Ciater, Darajat, Kamojang, Pangalengan, and Patuha are significant landmarks in the region. (Purnomo and Pichler, 2014). In contrast, the Tertiary volcanic belt is the primary location of fault-hosted geothermal systems. Volcanoes in the Quaternary volcanic belt are the exclusive locations for geothermal systems.

Figure 1 illustrates the authors' advanced approach to transforming geothermal resources into valuable minerals. The process strongly emphasizes silica recovery, which utilizes cutting-edge technologies like forward osmosis (FO), electrodialysis (ED), and ion sieve adsorption. This comprehensive strategy is carefully formulated to maximize the efficiency of extracting silica and lithium from geothermal brines while reducing environmental impact. FO is notable for its capacity to properly handle high-silica solutions, resulting in efficient separation and reduced energy usage compared to traditional processes. After the recovery of silica, the process of concentrating lithium ions is carried out by utilizing selective ion transport across membranes with the help of an applied electric field. This process improves the quality and strength of lithium in the brine. In addition, the process of ion sieve adsorption enhances the quality of the lithium product, resulting in a high level of purity that is well-suited for a range of industrial uses, such as battery production. The combined employment of these cutting-edge technologies enhances the efficiency of mineral recovery rates and promotes the sustainable utilization of resources by minimizing waste output and optimizing energy efficiency. The authors' approach emphasizes their dedication to sustainable development in the geothermal industry, which aligns with worldwide environmental objectives and standards while ensuring the effective extraction of rich minerals from geothermal brines.

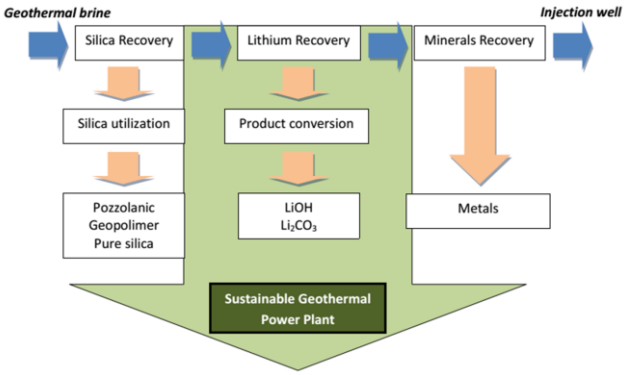

Figure 1: Processing concept of converting geothermal resources into valuable minerals.

3. SILICA RECOVERY

A significant obstacle in harnessing geothermal brine is the accumulation of silica, which can obstruct pipes and machinery, leading to operational complications (Figure 2). Efficient management and exploitation of silica are essential for avoiding these disturbances. The significance of thorough mineral extraction from geothermal brine is shown by converting this byproduct into a valuable resource. In addition to silica, precious minerals such as lithium can be mined, increasing economic value and promoting resource efficiency in the geothermal industry.

Extracting silica from geothermal brine is challenging but potentially fruitful in commercial settings. Geothermal brines include substantial amounts of dissolved silica, a naturally occurring mineral that, if not carefully controlled, can cause scaling problems in processing equipment and pipelines. Scaling is the process in which silica separates from the brine due to temperature, pressure, or chemical composition changes. This phenomenon leads to the formation of deposits that can impede flow, decrease heat transfer efficiency, and raise operational expenses.

Figure 2: Silica Deposition Clogging in Geothermal Power Plants.

An integrated strategy efficiently extracts silica from geothermal brines while addressing scaling issues. Initially, thorough pre-treatment operations are essential. The methods entail using filtration and sedimentation techniques to eliminate particles and impurities from the brine, decreasing the initial silica content and reducing fouling in subsequent equipment. Consistent surveillance and preemptive upkeep are crucial for a prosperous silica retrieval plan. By regularly analyzing the silica levels in the brine and closely monitoring scaling tendencies, operators may predict possible problems and promptly apply cleaning and anti-scaling treatments. This strategy extends the operating lifespan of equipment and guarantees continual production efficiency.

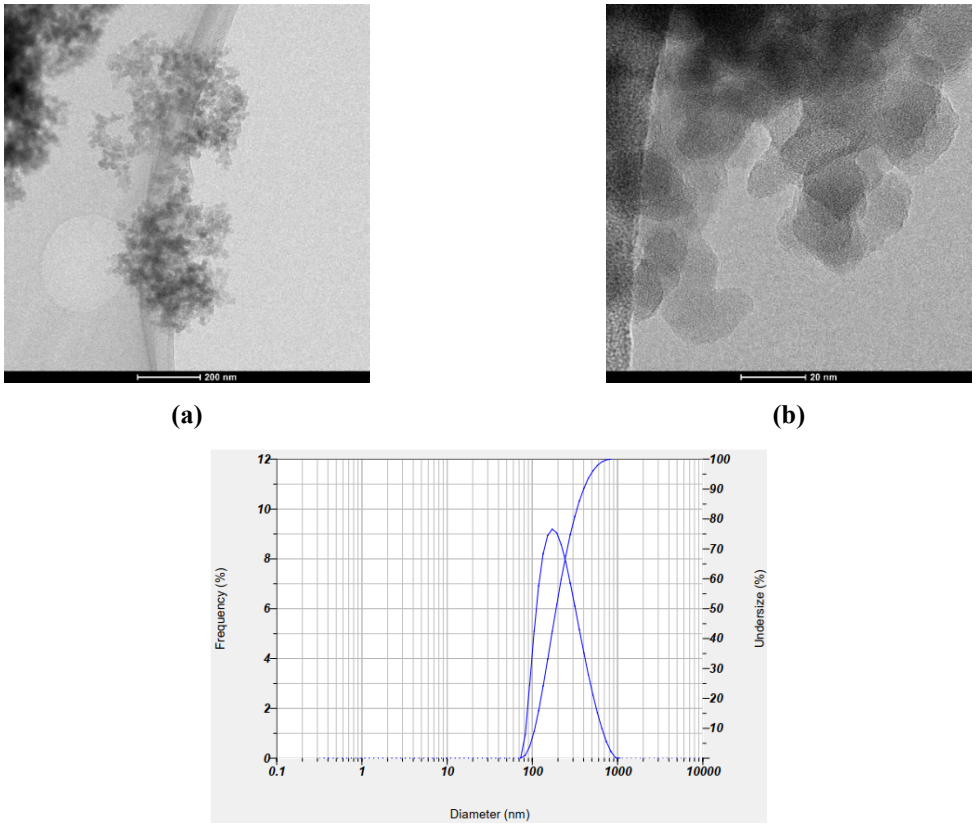
3.1 Nanosilica

Nanosilica is extensively utilized in various fields, including but not limited to thermal and electrical insulation, humidity sensing, chromatography, and catalysis (Hessien et al., 2009). Techniques for generating nanosilica include chemical precipitation, gas phase agglomeration, and the sol-gel technique. The sol-gel method and the chemical precipitation method are the two generally employed techniques. Hence, for this investigation, the chemical precipitation approach was selected. The chemical precipitation method involves the formation of a solid precipitate in a solution due to a chemical reaction. Precipitation typically happens when the amount of dissolved ions approaches the maximum level at which they may remain dissolved, causing the creation of a salt. The precipitation method is commonly performed concurrently, where the silicate solution and H2SO4 solution are combined simultaneously during the operation. Despite its limited usage, nanosilica has versatile applications

across multiple industries. Its applications include its utilization as a catalyst precursor, absorbent, and composite filter. In addition, nanosilica substantially impacts the structural strength of HVFA, which will be further elaborated on in the following section. Nanosilica materials use epoxy resin composites due to their advantageous qualities, including tensile, compressive, and shear strength.

Figure 3: Nanosilica product from geothermal silica.

By optimizing influential parameters such as pH and reactant ratios, the synthesis of nanosilica has been successfully achieved (Figure 3). The nanosilica achieved a maximum yield above 75% through thorough investigation and optimization of process parameters. Accurate pH regulation and appropriate proportions between the silicate solution and H_2SO_4 are crucial in attaining maximum effectiveness in nanosilica manufacturing. The results indicate that the chemical precipitation method employed in this work successfully generates nanosilica with a high yield, hence facilitating its extensive utilization across diverse industrial sectors. Particle size analysis is conducted using transmission electron microscopy (TEM) and particle size analysis (PSA) tests. The transmission electron microscopy (TEM) test is performed to examine the morphology of the product. The TEM test might be utilized in this scenario to verify the suitability of the PSA test conducted (Figure 4).



(a) **(b)**

(c)

Figure 4: TEM and PSA analysis, (a) TEM 200nm, (b) TEM 20nm, and (c) PSA.

The PSA test was conducted to ascertain the particle size of the nanosilica product that was produced. A product is classified as a nanoparticle if its size is less than 100 nm. According to the PSA nano silica test conducted under different working conditions, it can be concluded that the product obtained is not in the form of nanoparticles, as its size ranges from 181.1 nm to 280.1 nm. Nevertheless, upon TEM examination conducted on the identical

product, it is evident that the particles are still not represented at a size of 200 nm. The newly developed silica nanoparticles are visible at 20 nm, indicating that the end product can be categorized as a nanoparticle. According to estimates, the nanosilica particles are believed to form agglomerates, which means that the size measured by PSA analysis does not include the nanoparticles. Therefore, considering the various factors discussed earlier, it may be inferred that the product is a nanoparticle.

3.2 Silica gel

Indonesia is a significant consumer of silica gel, a highly coveted product globally. The demand for silica gel in Indonesia has been consistently growing and is expected to continue to rise, fueled by the country's robust consumer buying power. Indonesia has the potential to significantly increase the production of silica gel, which might lead to a reduction or complete elimination of the requirement for imports. It can potentially establish itself as a country that sells goods to other nations. This product is essential due to the extensive global need for silica gel in many industries.

Silica gel is a granular substance that resembles glass and has a very porous structure. It is created by synthesizing sodium silicate. The creation reaction of silica gel can be categorized into two distinct stages specifically (Ciriminna et al., 2013):

Hidrolisis: $Na_2SiO_3 + H_2O + 2HCl \rightarrow Si(OH)_4 + 2NaCl$ (1)

Kondensasi: $Si(OH)_4 + (OH)_4 Si \rightarrow (OH)_3 Si{-}O{-}Si(OH)_3 + H_2O$ (2)

Despite its name containing "gel," it is still categorized as solid silica. Silica gel is a preventative measure against excessive moisture by inhibiting its occurrence. Silica is a secure substance that helps retain moisture in various items such as food, medications, delicate materials, electronics, and even films. This product is frequently encountered in packages and shipments containing films, cameras, binoculars, computer equipment, leather shoes, clothing, food, pharmaceuticals, and other products. This hygroscopic compound absorbs moisture without changing its composition. Silica is a hygroscopic substance that can adsorb moisture and liquid particles from the surrounding air or spaces. Silica additionally aids in the prevention of harm to stored commodities. This hygroscopic substance also functions as a rust inhibitor for metals, mitigating the potential for short circuits in microelectronics and reducing the oxidation and degradation of chemicals due to elevated atmospheric humidity.

Figure 5: Silica gel product from geothermal silica.

The production of silica gel from geothermal brine has been effectively achieved by considering many factors, such as the concentration of the acid solution and the dilution of sodium silicate (Figure 5). This procedure produces silica gel with a high capacity for absorbing water vapor. Using geothermal energy to produce silica gel is cost-effective and environmentally sustainable, as it repurposes industrial waste for moisture management and protecting delicate items.

Silica gel was characterized using Fourier Transform Infrared (FTIR) spectroscopy to analyze its absorption bands. The FTIR analysis results (Figure 6) indicate a high degree of similarity in curve intensity with the silica gel white/SiO2 database, achieving a score of 851. This score surpasses other databases that may exhibit a similar infrared absorption intensity to the sample. This investigation presents data regarding the effective production of silica gel from geothermal silica utilizing the sol-gel technique.

The FTIR analysis results also provide information about the functional groups in the silica gel sample. Several peaks are observed in the frequency spectrum of the silica gel sample, as shown in Figure 6. At a frequency of 1055.86 cm^{-1}, it indicates the Si-O group, which signifies the vibration characteristics of SiO_4 and indicates the polymerization of Si-O-Si. The bending vibration at 1633.87 cm^{-1} also shows the presence of siloxane (Si-O) groups (Nuryono and Narsito, 2010). The broad band at the frequency of 3385.06 cm^{-1} represents the vibration of -OH groups (hydroxyl) originating from silanol (Si-OH) or hydrated water. Generally, the absorption bands appearing in the silica gel spectrum indicate that the functional groups present in silica gel produced from geothermal silica include silanol (Si-OH) and siloxane (Si-O-Si) groups (Sdiri et al., 2014).

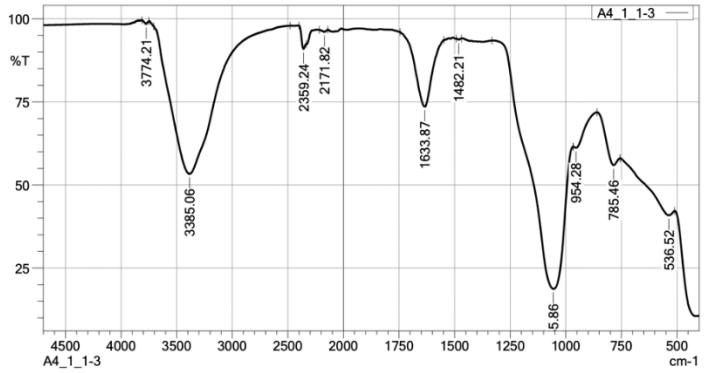


Figure 6: FTIR analysis result of silica gel.

3.3 Material Construction

The massive infrastructure development in the past decade has led to a continuous growth in demand for construction materials, including concrete. This fact has prompted various companies, both government-owned and private, to compete in creating high-quality concrete at competitive prices. According to data from the Indonesian Precast and Prestressed Concrete Association (AP3I), concrete production has shown an increasing trend each year. In 2015, the production capacity of concrete reached 25.30 million tons per year, and it further increased in 2017 to 35 million tons per year. It is estimated that these numbers will continue to grow in the future, considering that Indonesia is one of the countries that may still develop its infrastructure.

Concrete construction materials utilizing HVFA (High Volume Fly Ash) can be produced by combining coal fly ash with silica and incorporating a base activator like sodium hydroxide (NaOH). HVFA concrete is a composite material composed of pozzolan and activator. Pozzolan is a substance that consists of silica and alumina. Aluminum and silicon-containing materials are treated with very concentrated alkaline solutions to activate them (Palomo, Grutzeck, and Blanco, 1999). The reference is from Palomo, Grutzeck, and Blanco's work published in 1999. Fly ash waste is utilized as a binding agent in concrete compositions. Sodium hydroxide and sodium silicate are commonly employed as activators. Sodium silicate acts as a catalyst to speed up the polymerization reaction.

In contrast, sodium hydroxide reacts with the aluminum (Al) and silicon (Si) atoms present to form robust polymer bonds (Hardjito, 2005). Increasing the molarity leads to a corresponding increase in compressive and splitting strength. Nevertheless, it has been discovered that HVFA concrete exhibits more brittleness compared to standard concrete (Ekaputri and Triwulan, 2013). Like cement, fly ash mixed with alkali activators requires time to react and eventually harden. The testing of setting time in cement is influenced by the type of cement used and the amount of water used. In the case of fly ash, the setting time is greatly influenced by the grade of fly ash used, the ratio of fly ash to alkali activator, and the level of molarity of the alkali activator used.

Criado et al. (2007) demonstrated that a high amount of reactive silica triggers the formation of a higher quantity of geopolymer gel, which in turn enhances the mechanical strength of concrete (Criado et al., 2007). On the other hand, the distribution of particle size has a significant impact on the reactivity of fly ash. A higher number of fine particles will result in a larger surface area and a higher reactivity, leading to a greater compressive strength (Diaz, Allouche, and Eklund, 2010). The addition of nanosilica in Portland cement concrete systems has been extensively investigated, and it has been found that nanosilica can be used as an additive. Nanosilica has a positive influence on the mechanical properties of concrete (Phoo-ngernkham et al., 2014). It is expected that the addition of nanosilica will also have a positive impact on extreme environmental conditions.

Concrete production with nanosilica has been successfully achieved by including many contributing components, such as the fly ash-to-cement ratio (Figure 7). The analysis has achieved optimal circumstances, leading to a compressive strength of 26.9 MPa and a 2547 kg/m³ density for High Volume Fly Ash (HVFA) concrete. This achievement significantly exceeds the quality standard established by SNI DT 91-0008-2007 for K225 concrete, which mandates a compressive strength of 19.3 MPa. The findings suggest that including nanosilica in the concrete mixture can significantly enhance its mechanical characteristics, broadening its construction applicability through increased strength and density.

FTIR analysis was also conducted in this study. In Figure 8, FTIR spectra of HVFA concrete samples exhibit peaks in the wavenumber regions of 900 – 1300 cm^{-1}, 1650 cm^{-1}, and 3400 – 3650 cm^{-1}, resembling groups typically found in zeolites. The Si-O-T group observed at wavenumbers of 900 – 1300 cm^{-1} indicates the presence of copolymerization reactions. These peaks suggest the existence of silica-alumina bonds characteristic of zeolite-like structures within the HVFA concrete matrix. The FTIR analysis offers detailed insights into the chemical bonding and structure of the concrete, emphasizing the incorporation of nanosilica and its role in forming these

distinctive functional groups. This characterization highlights the potential enhancement of concrete properties through nanosilica addition, thereby improving performance and durability in various construction applications.

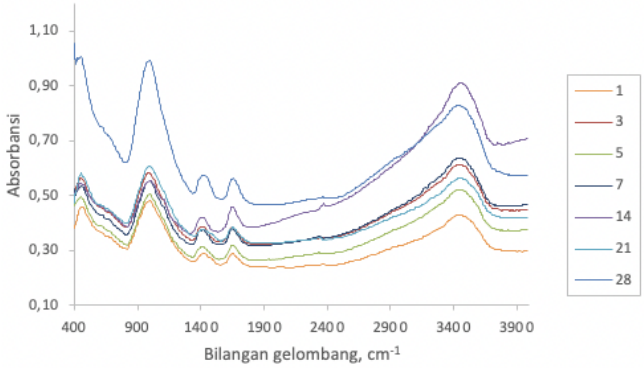

Figure 8: FTIR analysis result.

4. LITHIUM RECOVERY

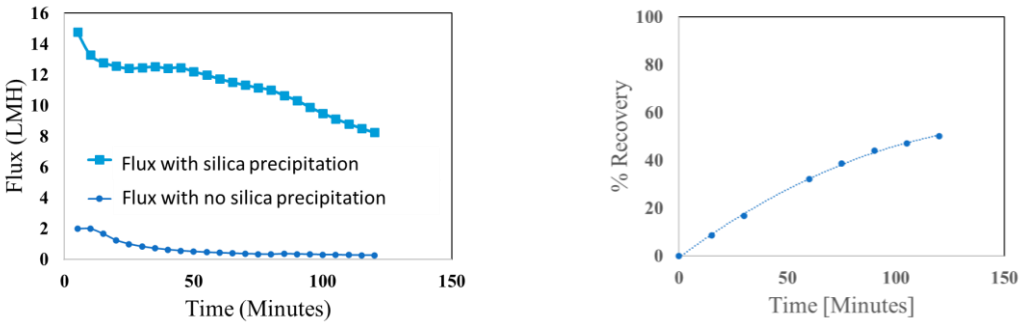
Lithium can be acquired from two distinct sources: natural sources, including minerals, salt lakes, subterranean water, and seawater, as well as artificial ones, such as recycling operations involving electronic trash and lithium batteries (Siekierka dkk., 2018). Lithium is an element that is not commonly discovered, although it can be found in certain rocks and certain sea waters. However, its presence is always in tiny amounts. The average concentration in the Earth's upper crust has been calculated to be approximately 60 parts per million (ppm) and is ranked 27th in element abundance (Garrett, 2004). The lithium concentration process commonly relies on solar evaporation as the primary technique. Despite its simplicity, the conventional method of salt manufacture from brine, as practiced by salt farmers, remains highly susceptible to weather conditions. Solar radiation is the primary catalyst for saltwater vaporization, resulting in salt formation (Flexer dkk., 2018). Developed countries have started designing membrane technology to extract essential minerals like lithium. A pressure-driven membrane separation method involves the application of a pressure difference across a membrane. This pressure difference might take the form of microfiltration (MF), ultrafiltration (UF), nanofiltration (NF), or reverse osmosis (RO).

4.1 Forward osmosis

In osmosis, water diffuses through a selectively permeable membrane from a region of higher chemical potential to a lower chemical potential. This phenomenon arises from the gradient in solute concentration across the membrane, which generates a driving force. There are various well-known applications of this phenomenon, such as reverse osmosis (RO), pressure retarded osmosis (PRO), and forward osmosis (FO). Water treatment technologies have generally widely employed reverse osmosis (RO). The utilization of reverse osmosis (RO) for treatment purposes is often accompanied by notable economic drawbacks, including elevated membrane fouling rates and substantial operational energy expenses resulting from the requirement of external pressure to traverse the permeable membrane. On the other hand, the forward osmosis (FO) process, which is also a type of osmotic process, has benefits that are not present in reverse osmosis (RO) (Cath et al., 2006).

In the process of forward osmosis (FO), the draw solution (DS) serves as the driving force to counterbalance the osmotic pressure, enabling water to flow through the permeable membrane without requiring external pressure, as is the case in the reverse osmosis (RO) process. The features of the DS substantially determine the effectiveness of the FO process, and there are numerous crucial criteria for selecting it. Initially, the DS should possess a

comparatively elevated osmotic pressure. The DS must also be easily reconstructable after surgery. Finally, the DS must reduce the focused pressure on a single membrane side (Zhao et al., 2012). In Forward Osmosis (FO), the Draw Solution (DS) undergoes two stages: initial dilution and subsequent concentration. During the initial phase, a substance with elevated osmotic pressure absorbs water from the feed. The diluted substance is reconcentrated in the following phase using alternative methods (Long et al., 2018). After a more thorough analysis, it has been shown that the second stage plays a pivotal role in improving the operation's energy efficiency.



(a) (b)

Figure 9: Graphical insights from optimized lithium recovery study results using forward osmosis technology for (a) flux and (b) recovery percentage (Mustika et al., 2022; Sutijan et al., 2022).

The investigation of forward osmosis (FO) for the purification of geothermal brines with lithium has yielded encouraging findings (Figure 9), namely in terms of achieving a lithium recovery rate of roughly 50% and attaining a greater flux (around 38 LMH) compared to alternative membrane approaches. Nevertheless, there are substantial obstacles that must be confronted during the implementation of this technology. Before the forward osmosis (FO) procedure, it is necessary to eliminate silica present in geothermal water. It is essential to take this step because silica can create fouling and the buildup of material on the membrane surface, which decreases process efficiency and requires frequent membrane cleaning for maintenance purposes.

Forward osmosis (FO) has been determined to have a higher propensity for fouling in comparison to other membrane technologies, such as nanofiltration (NF) and reverse osmosis (RO). Fouling is commonly ascribed to the presence of suspended particles and organic matter in geothermal solutions. Hence, FO systems should incorporate efficient tactics to reduce and control fouling, such as careful membrane selection and effective pretreatment techniques. However, FO's benefits in extracting lithium and its ability to handle more significant amounts of fluid flow have great potential in treating geothermal water. Forward osmosis (FO) may offer a more energy-efficient and environmentally sustainable alternative to existing technologies such as reverse osmosis (RO), particularly considering the growing scarcity of water resources and the increasing demand for lithium in batteries and electronic industries. Future research endeavors could enhance the efficiency of forward osmosis (FO) by optimizing operational conditions, enhancing fouling resistance, and minimizing total operational expenses. This endeavor will bolster the competitiveness of forward osmosis (FO) technology in geothermal water treatment and lithium extraction in the coming years.

4.2 Electrodialysis

Electrodialysis (ED) is a method that involves the movement of ions across a membrane as a result of an applied electrical potential difference and the flow of electric current (Mulder, 2003). Typically, ED experiments are conducted using an electrodialysis stack consisting of a cation exchange membrane (CEM), an anion exchange membrane (AEM), an anode electrode (e.g., iridium-coated titanium), and a cathode electrode (e.g., stainless steel) (Nie et al., 2017). Multiple investigations have demonstrated that Li^+ ions can permeate the monovalent ion exchange membrane, moving from the brine (feed) to the concentrate (purified solution) due to an electric driving force during the process. Conversely, ions like Mg^{2+} and Ca^{2+} cannot pass through the monovalent ion exchange membrane and remain in the feed solution (Zhang et al., 2020). Hence, electrochemical deposition (ED) demonstrates significant promise in lithium extraction, particularly in brine separation.

According to various research, the electrodialysis (ED) approach offers several benefits in comparison to alternative techniques for separating membranes (Van Der Hoek et al., 1998; Post et al., 2007; Walha et al., 2007). Electrodialysis significantly benefits conventional membrane separation technologies by requiring minimal feed preparation. This result is achieved through reverse polarity operation, which minimizes membrane fouling and scaling. Furthermore, electrodialysis allows far greater brine concentrations due to the absence of any restrictions

imposed by osmotic pressure. The ion exchange membrane's chemical and mechanical stability ensures a prolonged lifespan, especially when exposed to harsh and oxidizing components in the feed water.

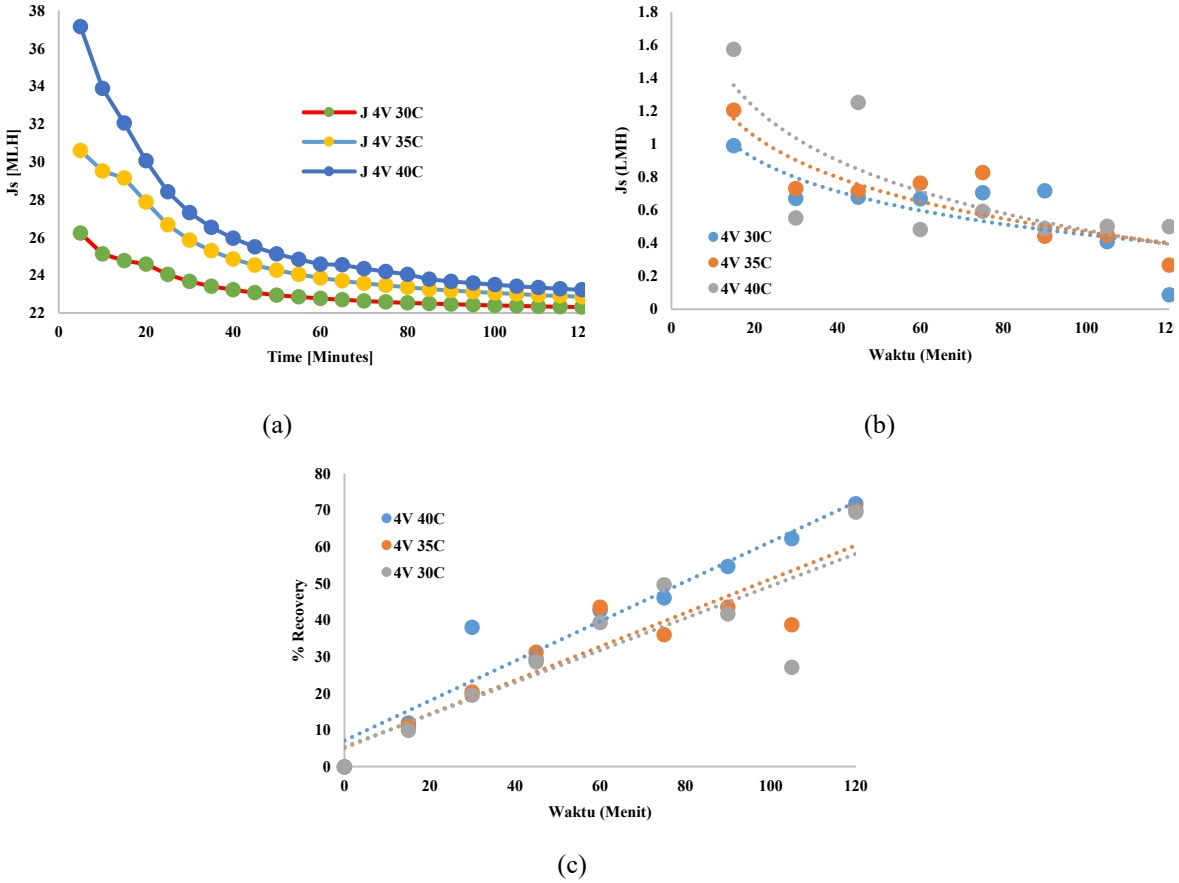


Figure 10: Graphical insights from optimized lithium recovery study results using electrodialysis technology for (a) solution flux, (b) ionic flux, and (c) recovery percentage (Jati et al., 2023; Sujoto et al., 2022).

Electrodialysis for lithium extraction has demonstrated considerable promise within the industry. Electrodialysis employs an electric field to segregate lithium ions from the solution using ion-selective membranes. While the flux generated may not be as substantial as that of alternative membrane technologies, the recovery percentage surpasses 70%, as evidenced in Figure 7. These findings render electrodialysis a compelling substitute for traditional separation technologies. An essential benefit of electrodialysis is its notable separation efficiency. The electric field employed in this procedure can efficiently extract lithium ions from the solution, enabling a remarkably effective separation. The high accuracy of ion-selective membranes guarantees the precise separation of lithium ions from other ions in the solution, improving the end product's quality. This phase is essential for industrial and battery applications where the purity of lithium is of utmost importance.

Moreover, electrodialysis has excellent scalability and may be seamlessly combined with other separation technologies to enhance the overall efficiency of the extraction process. This method is scalable and may be adapted to suit the requirements of various sectors. It can also serve as a final step following initial separation processes utilizing alternative membrane technologies. The adaptability of electrodialysis makes it highly suitable for usage in diverse environmental situations and with varied brine sources. Electrodialysis offers the benefit of consuming less energy compared to alternative separation technologies. Although this method necessitates using an electric field that consumes energy, the technology has advanced to function with improved energy efficiency. Electrodialysis minimizes waste production, which is crucial in mitigating the environmental consequences of lithium extraction.

In general, while the flow generated by electrodialysis is not as substantial as that of other membrane technologies, this approach has great potential due to its high recovery rate, energy efficiency, and capability to manufacture lithium products with excellent purity. Research findings suggest that electrodialysis has the potential to play a significant role in future lithium extraction methods. It offers a practical and eco-friendly option for the fast-growing lithium sector.

4.2 Ion sieve adsorption

A sieve ion adsorbent is an inorganic substance that utilizes redox reactions, ion exchange, or heating processes to incorporate template ions into inorganic compounds, forming oxide compounds. These processes can be conceptualized as a fusion of oxidation and reduction. Subsequently, the eluent will displace the template ion from its crystalline location, while the vacant crystal sites will remain intact. Consequently, traditional crystal sites can only accommodate ions with ionic radii equal to or smaller than the target ion's structure when forming inorganic materials. This constraint guarantees that inorganic materials are incapable of incorporating additional ions. These chemicals are inclined to attract template ions and tend to create the most favorable crystal structures.

Consequently, the template ion exhibits both a memory effect and a reliable filtering function, allowing it to adsorb the target ion even in the presence of numerous ions. The phenomenon is referred to as the ion sieve effect. An ion sieve technology selectively permits the passage of just lithium ions because it possesses the smallest ionic radius among all metal ions.

The adsorbent is a crucial component of the adsorption process. Therefore, the selection of the adsorbent is also vital in this study. The categorization of adsorbents for the lithium recovery process, as described by Safari et al. (2020), can be classified into (Safari, Lottermoser, and Alessi, 2020):

- Ion-imprinted polymer sorbent is made from functional polymerized hydrophilic monomers whose target is to capture the expected or taken ion.
- Metal oxide sorbent is made of metal and divided into manganese, titanium, and aluminum.

Unlike ion-imprinted polymer sorbents, metal oxide sorbents provide several advantages. They are easy to synthesize, highly selective for lithium, and may be easily extracted from the adsorbent (Safari, Lottermoser, and Alessi, 2020). Nevertheless, the metal oxide sorbent is not yet considered the optimal adsorbent material for lithium recovery from brine due to existing challenges in enhancing chemical degradation and sorbent lifecycle. These improvements are necessary for achieving better performance and enabling widespread commercial production. This study will utilize a titanium-based adsorbent due to its specific lithium affinity. Theoretically, the titanium basis has a maximum adsorption capacity of 127 milligrams per gram, but the manganese base can only retain up to 68 milligrams per gram (Lawagon et al., 2016).

The choice of ion sieve adsorption was based on its favorable characteristics, including low toxicity, low cost, excellent chemical stability, and high lithium adsorption capacity. This adsorbent is usually the most promising choice (Weng et al., 2020). The ion sieve adsorption procedure necessitates the use of an adsorbent material. This material has undergone thorough investigation on a global scale to identify the most effective adsorbent for lithium recovery. A highly favored adsorbent is metal oxide due to its exceptional affinity for lithium and its efficient absorption during manufacturing. Ion sieve adsorption can be categorized into lithium manganese oxide (LMO) and lithium titanium oxide (LTO). This investigation will utilize LTO. Current research on ion sieve adsorption continues to prioritize the usage of manganese-based ion sieves. This approach has limitations: the structure is susceptible to breakage and has substantial solute loss. Titanium-based ion sieve adsorption effectively addresses the drawbacks of manganese-based ion sieve adsorption, including reduced loss and a stable structure (Shi et al., 2013).

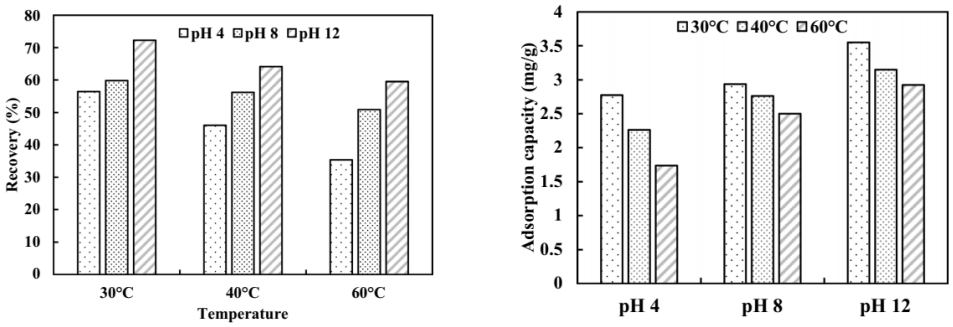

Figure 11: Graphical insights from optimized lithium recovery study results using ion-sieved adsorption technology (Tangkas et al., 2023).

The study aimed to examine the impact of temperature and pH fluctuations on the adsorption capacity of a lithium adsorbent (Figure 11). Under optimum temperature and pH settings, the analysis revealed a lithium adsorption capacity of 3.55 mg/g and a recovery efficiency above 70%. This work holds great importance because of the substantial significance of lithium in lithium-ion battery applications and other energy-related businesses.

Enhancing the effectiveness of the lithium adsorption and recovery process can be achieved by improving adsorption conditions, such as temperature and pH.

Regarding future advancements, there are possibilities to investigate improving the stability and augmenting the adsorption capacity of the adsorbent. To enhance stability, one can change the structure of the adsorbent or include functional groups to improve endurance under different pH and temperature circumstances. One can pursue material changes or surface engineering approaches to increase the surface area or introduce specialized binding sites for lithium ions to enhance the adsorption capacity. These developments aim to improve lithium recovery techniques' effectiveness and long-term viability, supporting the broader objectives of expanding sustainable energy systems that depend on lithium resources. Subsequent investigations could prioritize expanding these enhanced adsorption methods for use in industrial settings, thus tackling the increasing need for lithium while mitigating ecological consequences.

4. ECONOMIC POTENTIAL OF MINERAL EXTRACTION FROM GEOTHERMAL RESOURCES

The economic viability of mining minerals from geothermal resources has emerged as a prominent subject in the worldwide discussion on energy and resources. Due to the rising market value of essential minerals like silica and lithium, the renewable energy sector emphasizes the economic opportunities associated with developing and utilizing these resources. PT. Geo Dipa Energi, a prominent participant in this sector, demonstrates the potential for substantial financial gains by using cutting-edge technologies to extract and purify minerals from geothermal brines. In addition to the financial advantages, these initiatives can improve energy self-sufficiency and decrease carbon emissions, fostering new economic prospects and facilitating the shift towards a more sustainable economy based on natural resources.

	SiO2	Li	Na	K	B	Ca
Low Price	51,44902928	12,27364431	6,122734194	2,144692137	1,062312337	0,097780746

Figure 12: Potential annual profits from each valuable element by PT. Geo Dipa Energi.

Figure 12 presents a comprehensive summary of PT. Geo Dipa Energi's anticipated yearly earnings from extracting precious components from geothermal resources. Silica is the top performer in profitability, with an expected annual profit of almost $169 million. The prominence of silica recovery in their processing method emphasizes its strategic importance due to its strong market demand and economic worth in diverse industries such as glass manufacture, electronics, and construction materials. Advanced techniques such as forward osmosis, electrodialysis, and ion sieve adsorption are used to extract and purify silica. These technologies ensure efficient use of resources and minimize environmental impact.

Lithium is expected to generate approximately $28 million in annual sales, making it a significant source of income after silica. The growing need for lithium in batteries for electric vehicles and renewable energy storage systems enhances its economic importance. Advanced extraction methods are utilized to concentrate and purify lithium from geothermal brines, improving its quality and making it more suitable for the market. In addition, Figure 12 illustrates the possible financial gains from additional precious minerals, including sodium (Na), potassium (K), boron (B), and calcium (Ca), all of which play a substantial role in determining the economic viability of the project. These minerals are used in several industries, including agriculture (as fertilizers), pharmaceuticals, and industrial operations. Thorough extraction and processing methods are employed to optimize the retrieval of these precious materials and guarantee the implementation of sustainable resource management techniques.

The anticipated financial gains depicted in Figure 12 highlight the dedication to utilizing geothermal resources for economic benefit while upholding principles of environmental sustainability. The objective is to become a prominent player in sustainable mineral extraction from geothermal brines by concentrating on valuable minerals

such as silica and lithium. This result will be achieved through advanced technologies and efficient processing methods. Doing so aims to positively contribute to economic growth and environmental stewardship in the energy sector.

5. CONCLUSION

This study investigates an innovative method for harnessing geothermal energy by collecting minerals from geothermal brine to promote a circular economy. The technologies described for extracting lithium and silica from geothermal brine show great promise in converting waste into valuable minerals. The study focuses on novel extraction techniques and assesses the environmental consequences of these methods. This work significantly adds to the advancement of geothermal operations' sustainability by transitioning from a single-purpose energy production model to a multifunctional resource recovery approach. This approach is anticipated to decrease dependence on traditional mining methods and improve the effectiveness of utilizing natural resources.

Furthermore, adopting the concepts of the circular economy has the potential to broaden the economic advantages of geothermal energy beyond just energy generation. This research highlights the positive economic prospects of incorporating geothermal energy into a circular economy framework. The goal is to not only safeguard the environment but also to promote local economic growth and ensure sustainable resource management for the long term.

ACKNOWLEDGEMENTS

The authors thank Universitas Gadjah Mada (UGM) for providing the necessary facilities. The study of extracting rich minerals from geothermal brines has been dramatically advanced by UGM's essential contributions. In addition, the authors express gratitude to the Indonesian Ministry of Research and Technology/National Research and Innovation Agency (BRIN) for providing their facilities. The facility support offered by BRIN has been crucial in promoting the progress of this project. The authors would like to express their appreciation to PT. Geo Dipa Energi for their valuable support in supplying geothermal brine waste and silica.

CONFLICT OF INTEREST

The authors declare that they have no conflict of interest.

ABSTRACT

The Minahasa volcanic field is blessed with significant geothermal potential, demonstrated by the operational success of the 120 MWe Lahendong Geothermal Power Plants. Within the Minahasa Regency, Tompaso stands out as a sub-district characterized by an agrarian lifestyle deeply rooted in cultural heritage. Situated at an elevation of 800 meters above sea level, the fertile soils of Tompaso provide an ideal environment for agriculture.

The sustainability of geothermal operations hinges on a delicate balance of social harmony, environmental stewardship, and effective governance. PT Pertamina Geothermal Energy Tbk Area Lahendong endeavors to foster this balance by repurposing deposits from geothermal brine, previously regarded as waste. Collaborative research conducted by Universitas Gadjah Mada and PT Pertamina Geothermal Energy Tbk Area Lahendong reveals that the interaction between fluids and rocks within the Lahendong geothermal system yields deposit rich in approximately 60 elements and compounds, mirroring those found in volcanic ash. Through nanotechnology processing, these deposits are transformed into liquid booster, offering a promising alternative to chemical fertilizers and pesticides, as well as organic manure, which can pose long-term environmental challenges. The diverse array of compounds and elements presents in the geothermal deposit, including those from the oxide group, alkali metals, alkaline earth metals, basic metals, semi-metals, non-metals, lanthanides, actinides, and transition metals, are all vital for plant growth and development, with silica playing a particularly crucial role in reinforcing plant structures. Drawing inspiration from the traditional Minahasan couple dance known as "Katrili," the booster, applied through alternating pouring and spraying methods, is aptly named "Katrili." Developed as a fusion of Minahasan and European arts, the Katrili dance originally served as a celebration of gratitude for agricultural abundance and successful trade.

In Indonesia's agricultural sector, fertilizer scarcity poses a significant challenge. Thus, the innovation of repurposing geothermal by-products into a liquid booster does not only address the welfare of farmers but also enhance the environmental sustainability of geothermal energy production.

1. INTRODUCTION

1.1 Minahasa Volcanic Field

Minahasa district is situated in a volcanic field (Figure 1) in the northern arm of Sulawesi, which is part of the Sangihe volcanic arc (Hamilton, 1979). This NE-SW trending volcanic arc includes Mts. Ambang, Soputan, Lokon, Mahawu, Tangkoko, Ruang, Karangetang, and Mt. Awu, extending to the volcanic islands in the north (Hamilton, 1979).

The prominent volcanic structure in the area is the structurally controlled, 20 X 10 km2 Tondano Caldera (Lecuyer et al., 1997), within which the Lahendong Geothermal Working Area (GWA/WKP) is situated. Recent volcanic activity in Minahasa includes the eruptions of Mts. Soputan, Lokon, and Mahawu, providing fertile volcanic soils.

The Lahendong Geothermal Working Area (GWA/WKP), determined based on the Decree of the Minister of Mineral Resources Number 2067 K/30/MEM/2012 is partly located in the Minahasa Regency. The Tompaso sector of the Lahendong GWA is water-dominated, with the reservoir temperatures ranging from 260°C to 300°C. The heat source is believed to be igneous rock bodies beneath the Sempu volcano and other smaller volcanic cones. The development of the geothermal energy sector in Lahendong runs side-by-side in harmony with agricultural activities in the Minahasa Volcanic Field.

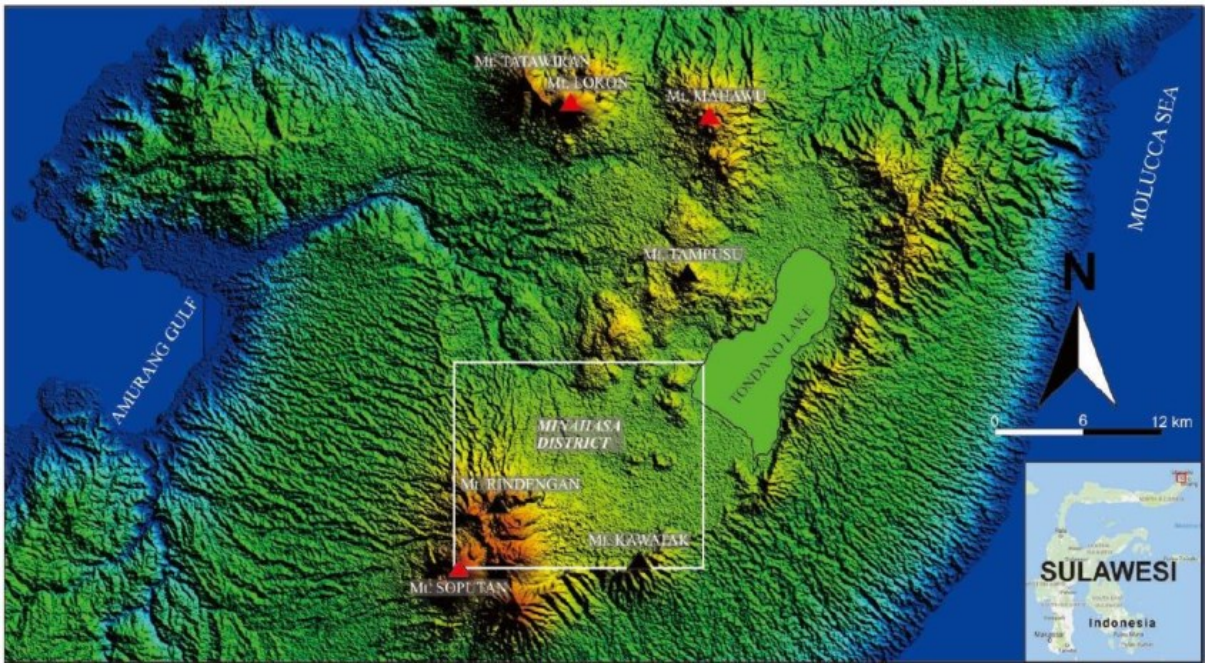

Figure 1: Location of the Lahendong Geothermal Area (outlined by the white curve) in the Digital Elevation Model base map (Badan Informasi Geospasial, 2024) showing its spatial association with the Tondano Lake and the volcanoes.

Figure 2: Brine canals with silica deposits in the Tompaso sector of the Lahendong GWA.

1.2 Geothermal Deposit

The natural fluid-rock interaction processes in the subsurface enrich the geothermal fluids in parts of the Lahendong geothermal field with silica and other compounds and elements (Utami et al., 2015; Utami et al., 2021). Consequently, some geothermal wells operated by PT Pertamina Geothermal Energy Tbk Area Lahendong produce fluids containing these dissolved components, which gradually deposit upon cooling. In a closed-loop system, before the geothermal fluid is reinjected into the reinjection well, it passes through the brine canals (Figure 2), leading to a buildup white sludge over time. This white sludge, generally referred to as silica deposit, was previously considered to have no added value and potentially harmful to geothermal production equipment if not removed regularly. However, our research shows that the deposits from Lahendong geothermal fluids contain numerous elements and compounds similar to volcanic ash. These elements and compounds are essential for supporting plant growth.

1.3 Minahasa Agricultural Activity

Most of the population in Minahasa district earns a living as farmers. The agricultural products in Minahasa Regency include lowland rice, corn, shallots, chilies, cayenne peppers, tomatoes, coconuts, and cloves. They are economically attractive and hence serve as the main source of income for the region.

Like other regions, North Sulawesi is experiencing a fertilizer shortage, leading to hardship for farmers due to the high price of the fertilizer in the market. This condition is predicted to persist for a long time due to the Russian-Ukrainian war, which has been causing shortage of chemical supplies for chemical fertilizer and pesticide industries.

The above situation provides a way for the geothermal industry to contribute to helping the agricultural sector. We process Lahendong geothermal fluid by-products into liquid fertilizers and plant enhancers/boosters by applying nanotechnology. This approach transforms silica deposits into a product with strategic and economic value that help meet farmers' needs and introduces a new perspective: "geothermal by-products are a blessing for farmers".

1.4 Naming the Product

To introduce the liquid booster developed from geothermal by-products from Lahendong GWA by PT Pertamina Geothermal Energy Tbk Area Lahendong in collaboration with Universitas Gadjah Mada, we and the local farming community name it "Katrili". This name reflects the method of applying the fertilizer and booster simultaneously, involving both watering and spraying, which can be compared to a pair of Katrili dancers moving in unison to the rhythm (Figure 3). The Katrili dance, an acculturation of European and Minahasa cultures, is deeply embedded in the social life of the community. It was introduced by the Portuguese traders, who came to North Sulawesi to buy agricultural products from the locals. Even in modern times, the Katrili dance is performed at various events, including “Pengucapan Syukur” (Thanksgiving) celebrations for abundant harvests (Wenas, 2007).

Figure 3: An illustration of the Katrili dance.

2. KATRILI FERTILIZER/BOOSTER

2.1 Geochemical Analysis of Geothermal Deposits

Deposits taken from the cooling ponds of Geothermal Power Plant units 1-4 (Lahendong sector) and units 5&6 (Tompaso sector), were analyzed. XRD analyses indicate that the deposits are dominated by amorphous silica and some salts. Geochemical analyses show that they contain about 60 elements and compounds including oxides, alkali metals, alkaline earth metals, and rare earth metals, essential for plant growth and development. Synthetic fertilizers available in the market do not have such a complete set of important constituents. The concentrations of the oxides in the geothermal deposit from Lahendong are comparable to the composition of volcanic ashes from Soputan (Budi et al., 2019) and Ibu (Saing et al., 2014) as presented in Figure 4.

2.2 Formulation and Composition of the Liquid Booster

"Katrili" fertilizer/booster is formulated and processed by applying nanotechnology such that the particle is so small and will not clog the nozzle of the sprayer. Particle size characterization is conducted using a Particle Size Analyzer (PSA) as a measure of quality control. The "Katrili" resulted liquid booster was diluted and analyzed. The ready to use liquid contains silica and bicarbonate as the dominant constituents, and other essential and trace elements. No harmful elements present within the threshold permitted for application to plants.

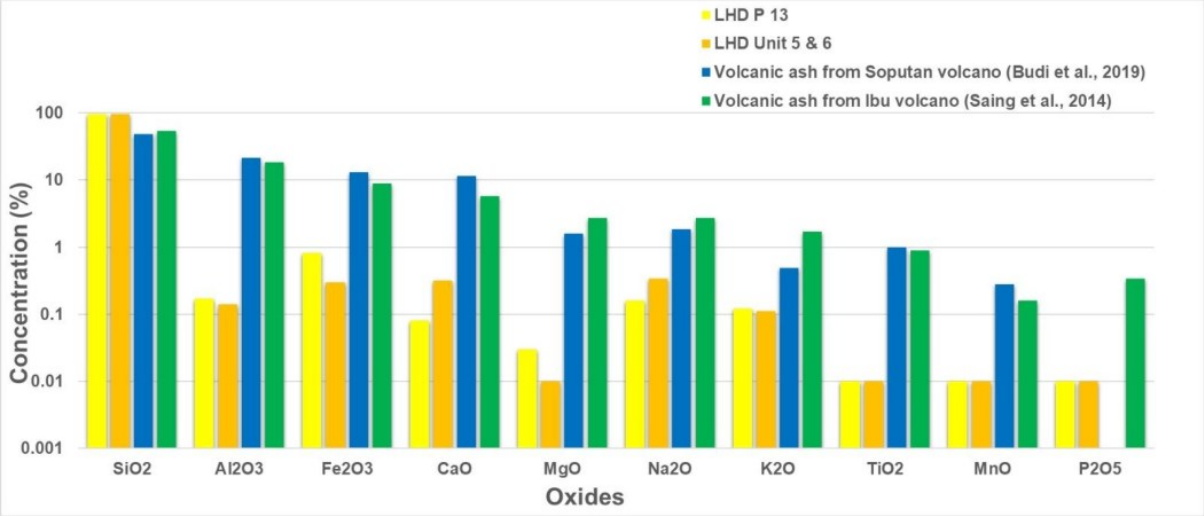

Figure 4: Bar chart showing the oxide compositions of the samples of the Lahendong geothermal deposits and volcanic ashes from Soputan and Ibu volcanoes.

2.3 Application

Each hectare of horticultural plants requires 10 liters of liquid fertilizer and booster for each application. As a fertilizer, the "Katrili" is poured into the soil once a month during the planting period, using a dose of 1 liter of fertilizer diluted with water to reach a total volume of 100 liters. As a plant strengthener, the "Katrili" is sprayed on plants every other week during the growing period, using a dose of 1 liter diluted with water to reach a total volume of 20 liters.

3. DEMONSTRATION PLOTS

Three demonstration plot (demplot) or designated area of land used as a model for agricultural practices, are prepared to showcase various planting and treatment designs. The planning and establishment of demonstration plots are crucial to exemplify environmentally friendly planting systems to the community. The locations and the design of each demonstration plot, as well as the preferred plant and planting patterns were established during focus group discussions (FGD) conducted beforehand with the partner farmers. The demonstration plots utilize the participating farmers' land located within the geothermal operation area in the Tompaso sector (Figure 5). Every plot is divided into 2 m X 2 m compartments, each is designated for specific treatment.

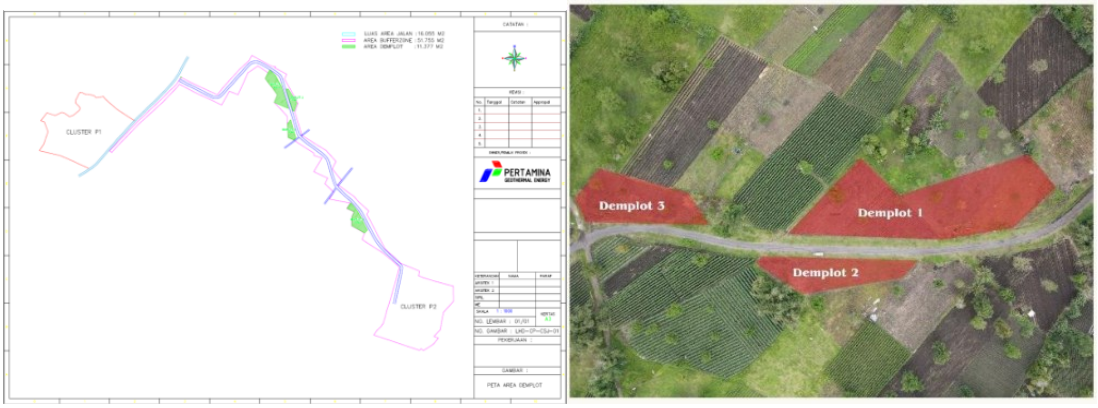

Figure 5: (Left) Map showing the location of the demonstration plots with respect to the clusters of geothermal wells P1 and P2. (Right) Aerial photograph of the demonstration plots.

The plant chosen for testing the effectiveness of Katrili fertilizer and booster is tomato, as the Tompaso Farming Community has been planting it during the time of our experiment. We distributed the “Katrili” liquid booster to two groups of participating farmers (example in Figure 6) who belong to the local church organizations, namely the Gereja Masehi Injili Minahasa (GMIM) and the Kerapatan Gereja Protestan Minahasa (KGPM).

Figure 6: Distribution of the "Katrili" liquid booster to the partner farmers in Tompaso.

The treatment using the "Katrili" booster is outlined in Table 1. Each treatment has been applied to a 2 m X 2 m plot and repeated 3 times, resulting in 18 experimental plots. Soil and plant samples will be collected from both the demonstration plots on farmers' existing land and the 2 m X 2 m plots before being treated, and during harvest, to analyze macro-nutrient (NPK) content, microorganisms, and heavy metal levels.

Table 1: Summary of the treatments applied to the demonstration plots in Tompaso.

No	Description	Symbol
1	Without Fertilizers and Pesticides	K
2	Existing Fertilizer + Pesticide	P1
3	Fertilizer + Existing Pesticides + Katrili	P2
4	Organic Fertilizer	P3
5	Organic Fertilizer + Katrili	P4
6	Chemical Fertilizer + Organic Fertilizer + Katrili	P5

4. FUTURE PLANS

The Tompaso farming community has shown interest in adopting the "Katrili" booster in their agricultural practices. The success of "Katrili" will meet their need for a locally available and environmentally friendly fertilizer and plant booster. Moving forward, we plan to work on large-scale production to commercialize geothermal by-products, utilizing both business-to-customer (B2C) and business-to-business (B2B) models to diversify the direct use of these by-products. We will explore opportunities for collaborative research and development between PT Pertamina Geothermal Energy Tbk Area Lahendong and Universitas Gadjah Mada to advance the production line.

ACKNOWLEDGEMENTS

The authors thank the management of PT Pertamina Geothermal Energy Tbk Area Lahendong and Universitas Gadjah Mada for their support of our research. We also express our gratitude to our partner farmers for their enthusiastic participation. Special thanks to Mr. Fatih Fauzi for his assistance in conditioning the samples prior to laboratory analyses and for drafting Figure 4. Additionally, we thank Mr. Tegar Narendra for creating the illustration of the Katrili dance used in the product labels and shown in Figure 3.

ABSTRACT

Central Java has the only high-enthalpy Geothermal Power Plant complex located in Dieng. The geothermal reservoir stretches across Sileri in the northwest, Sikidang, and Pakuwaja in the southeast. The Dieng area possesses tremendous geothermal energy potential, However, only 10.3% or around 60 MW of its potential is utilized. From the test results, hydrothermal in the Dieng area has mineral content that includes several elements, such as lithium 77.31-99.4 mg/l, silica 1,109.25 to 1,220.9 mg/l, boron 404.16-589.4 mg/l, potassium 2,532.2-4536.5 mg/l, and manganese 5.49-15.82 mg/l. At the moment, there is still a resource that has not been utilized, namely waste heat. Waste heat appears in the form of liquid-phase hydrothermal (brine) with a pH range of 6-7 and a temperature value of 180°C. The energy from the brine has the potential to be a source of water heating in hot spring facilities (balneology) with the help of heat exchanger technology. The process of flowing brine from geothermal production wells to heat exchanger machines around balneology facilities is carried out using pipes. The high mineral content in the brine causes scaling. Scaling on the pipe occurs due to the formation of deposits that can hinder the distribution of water and reduce the thermal conductivity and heat transfer coefficient. Therefore, PAC (Poly Aluminum Chloride) coagulant was used with a PAC concentration of 10 ppm, a pH value of 8, and the addition of Polyamide flocculant of 1 ppm. Then, the neutralized brine is used in the heat exchange system for balneology. The enthalpy of the geothermal working fluid is transferred to the heat pump working fluid (refrigerant) through the heat exchanger coil, causing the refrigerant to vaporize. Afterward, the refrigerant vapor is compressed to increase pressure and temperature. This high-temperature refrigerant is passed through the condenser pipe to warm the water in the balneology. As a result, the hot water from the heat exchange process has a temperature of less than 40°C and can be for hot baths. Hot baths can have physiological effects on the human body by inducing significant improvements in macro and microvascular functions. Hot baths can also trigger the release of endorphins, hormones that induce relaxation and sedation effects to resist drowsiness. Previous research also states that sleep quality becomes 100% better after a hot shower. The habit of taking a hot bath has a good impact on health, giving adequate sleep quality, lowering stress levels, and increasing happiness. The scheme of utilizing brine for balneological facilities can also enrich the tourism aspect of Dieng, open doors to economic activity, and improve social standards for the surrounding community.

1. INTRODUCTION

Tourism is one of the sectors that affect the development and increase of a country's income. Tourism is one of the world's most significant and fastest-growing economic sectors (Yakup, 2019). Dieng Plateau is a highland tourism area in Central Java located in Banjarnegara Regency and Wonosobo Regency, which is one of the leading tourist areas that has attractions offered in the form of natural and artificial tourism (Priyanto, 2016). The development of the tourism industry in this area is increasing, it can be seen from the increase in tourist attractions, in addition to natural tourism there is also artificial tourism or culinary tourism. Tourism is one of the sectors that affect the development and increase of a country's income. Tourism is one of the world's most significant and fastest-growing economic sectors (Yakup, 2019). The development of the tourism industry in this area is increasing, it can be seen from the increase in tourist attractions, in addition to natural tourism there is also artificial tourism or culinary tourism.

Figure 1: Dieng Tourism Region.

Hot springs or balneology is one type of tourism offered by Dieng. Currently, several places serve hot spring tourism in Dieng, including D'Qiano Hot Spring Waterpark, Toyabira, Sendang Sipandu, and Segar Asri (Aristyan, 2023). These hot springs come from the direct utilization of hot springs located around the tour, due to geothermal activity that occurs in the area. Dieng is an active volcanic area, whose heat from within the earth heats groundwater which then comes to the surface as hot springs. Direct utilization has the challenge that filtration needs to be done first so that the hot water used is safe and free from harmful substances (Herlambang, 2022). The location of hot springs is also influenced by geological factors, which are not available everywhere.

In addition, the Dieng area has great geothermal energy potential, although until now it has only been utilized by 10.3% of its total reserves or around 60 MW of the total geothermal energy potential of 580 MW in the region (Nurrochim, 2021). Currently, the Dieng geothermal field is managed by PT Geo Dipa Energi (Persero) which was established in 2002 to manage the assets of Himpurna California Energy Ltd (consisting of 1 unit of 55 MW geothermal power plant certified in 1998 and 27 wells) which were taken over by the government (Mazaya & Kurniawan, 2022). The Dieng geothermal field consists of 5 areas namely Sikidang area, Sileri area, Siglagah area, Sipandu area, and Bitingan area. The Sikidang area manifestation has an estimated temperature of 90°C with a pH of 2-3, the Sileri area has an estimated temperature of 80°C with a pH of 6, the Siglagah area has an estimated temperature of 70°C with a pH of 6-7, the Sipandu area has an estimated temperature of 80°C with a pH of 6-7, and the Bitingan area has an estimated temperature of 65°C with a pH of 6-7. In addition, Dieng geothermal also releases waste heat which is channeled through the separator outlet in the form of brine (Wisnu et al, 2020).

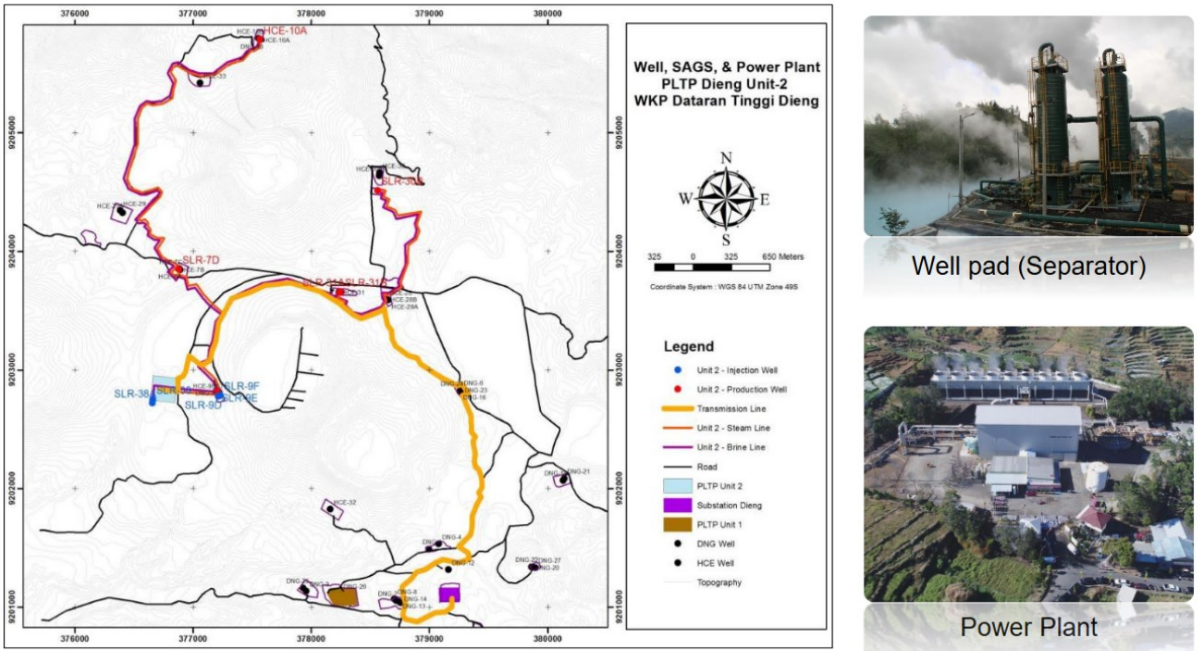

Figure 2: Location of Dieng Geothermal Field (Wisnu et al., 2020).

The challenges and obstacles faced in utilizing hot springs can be overcome through waste heat from the Dieng Geothermal Power Plant (PLTP). This paper focuses on how waste heat from the Dieng Geothermal Power Plant

can be utilized as an energy source for hot spring tourism (balneology), including the technical aspects and processes involved. In addition, this paper also includes economic and social analyses related to the application of this technology.

2. FIELD OVERVIEW

2.1 Trends in Balneology Usage

Balneology refers to the use of geothermal water for bathing and therapy. It is a long-established tradition that has existed for thousands of years. The Romans were perhaps the first to practice balneology as they already differentiated bathing for leisure and establishments for healing purposes (balneology). In Xiaotangshan Sanitarium, China, balneology has existed as a means of muscular and skeletal therapy for more than five centuries (Saptadji, 2019). Balneology presents in many forms as depicted below.

Figure 3: (a) Balneology for open-communal bathing, (b). Balneology as Mud-bathing, (c) Balneo-based Spa (Balneology Association of North America).

Most balneology presents in the form of open-communal bathing and, on some occasions, is developed for spas. Mud/ peat therapy commonly exists when geothermal water can mix with volcanic mud, creating a healing and mineral-rich source of balneotherapy (Smith and Puczkó, 2016). The Czech Republic classifies balneology as a central branch of rehabilitative treatment combined with a certain health regimen. Some other countries even include balneotherapy as an insurance-covered health service. However, there has been a shift in the intention of balneology site visitation due to the growing rate of tourism. In Hungary, the locals visit balneology sites for health and medical purposes. On the other hand, international tourists strive to visit the sites for pleasure and satisfaction. Germany, a place with strong-cultured balneology spas, has also changed the labeling of "spa for health" to "spa for wellness". In Indonesia, a glimpse of balneology can be seen in the picture below.

Figure 4: (a) Communal Bathing in Dieng, (b) Balneology-base Waterpark (Shoedarto et al., 2016).

Balneology may present as a medium to gain public acceptance of geothermal energy in Indonesia. Promoting a friendly and economically interesting way for the community to utilize the potential of geothermal energy (Shoedarto et al., 2016).

2.2 Balneology in terms of Health

The role of balneotherapy as a geothermal bathing area has various benefits to human health, especially for interconnected immune and psychological responses. The effects of hot baths on immunity are directly anti-inflammatory and immunosuppressive at the cellular level. In patients with induced atopic dermatitis, serum levels

of pro-inflammatory cytokines such as IL-1β, IL-13 and TNF-α decreased significantly after treatment with high concentrations of spring water. Treated patients also experienced modulation of inflammatory cytokines through an increase in anti-inflammatory IGF-1, while serum levels of pro-inflammatory cytokines TNF-α and IL-1β decreased. Patients with rheumatic diseases experienced reduced concentrations of prostaglandin E2 and leukotriene B4, and C-reactive protein after balneotherapy. Sulfur-containing hot baths can increase the level of Foxp3+ Treg cells that play a role in immunosuppressive activity. In addition, balneotherapy gives a positive influence to the oxidant/antioxidant system by reducing the production of reactive oxygen (ROS) and nitrogen which then impacts immunosuppressive activity (Maccarone et al., 2020).

Balneotherapy using iron-rich hot water and sulfuric acid chloride is ideal at 38-40 ℃, especially for cardiovascular responses. The correlation between balneotherapy and the ideal temperature is closely related to the difference in the body's response during hot and cold seasons. Balneotherapy in summer is only needed for a short time so as not to increase heart pressure excessively, while in winter balneotherapy activities need to be considered for duration to prevent a significant decrease in blood pressure (Wang et al., 2023).

The physiological effects on cardiovascular health were proven through case study-based research on 98 patients with musculoskeletal diseases. The treatment given was physiotherapy referral with balneotherapy. The results of the application of the method showed that diastolic pressure decreased and pulse rate increased, leading to good changes such as decreased pulse pressure and cardiac stress, and increased vascular elasticity (Sas et al., 2016). Thus, balneotherapy has the potential to reduce cardiac workload and increase vasodilation. However, the application of this therapy still requires attention to the risks that may be posed to certain body conditions. Individuals with potential chronic cardiovascular and lung diseases are recommended to perform balneotherapy in 1 cycle under 20 minutes (Wang et al., 2023).

2.3 Fluid Characteristics in Geothermal Dieng

The production fluids in the Dieng geothermal field are different from those in other geothermal fields in Indonesia. In addition to mostly being water, the fluids in Dieng have a high concentration of silica, about ± 900 mg/L. The Dieng Geothermal Reservoir has an installed capacity of 60 MW, divided into the Sileri and Sikidang areas (Wahyudityo et al., 2013). The Sileri area has neutral fluids, although there is a chance for magmatic fluids to mix in. Neutralization happens due to strong water-rock interactions within the reservoir. Temperatures here range from 283-338°C, with a chloride content of 69.22 mg/L. The fluid source is rainwater that has been heated, mixed with degassed magmatic fluids, boiled, and interacted with sedimentary or meta-sedimentary rocks (Kencana et al., 2024). The Sileri reservoir is characterized by high chloride content and a boron concentration of 3.84 mg/L, indicating interaction with sedimentary rock formations. Additionally, this reservoir has SiO2 and Fe concentrations of 41.09 mg/L and 0.12 mg/L, respectively. Other mineral contents include K at 21.3 mg/L, Ca at 13.69 mg/L, and Mg at 58.97 mg/L (Ramadhan et al., 2013). Hydrothermal fluids in the Sileri reservoir move vertically to the upflow zones in Pagerkandang Crater and Merdada Crater. The Sileri area also has a steam cap zone, characterized by excess enthalpy, high non-condensable gas (NCG) content, and a low water-to-steam ratio, which affects the overall efficiency of energy extraction. The presence of high NCG levels, primarily composed of CO_2 with traces of H_2S and CH_4, influences the steam chemistry and can lead to operational challenges such as scaling and corrosion in power plant equipment. These factors necessitate careful monitoring and management to optimize geothermal production and maintain reservoir sustainability.

The Sikidang area has more acidic fluids with a pH of 3.88, influenced by the dominance of magmatic fluids. This reservoir has two phases, with most wells reaching the steam cap zone and some wells reaching the liquid zone. A boiling zone is estimated between the liquid and steam reservoirs. Fluid temperatures in this reservoir range from 260-324°C, with high non-condensable gas (NCG) content, between 2-21%. Fluid flow in the Sikidang area comes from upflow zones around Pangonan Crater, Sikidang, and Sibanteng manifestations. These upflow zones are linked to acidic fluid zones, indicating potential acidic fluids deep within the reservoir (Kencana et al., 2024). The Sikidang reservoir has lower chloride and boron contents compared to the Sileri reservoir, with concentrations of 27.48 mg/L and 0.69 mg/L, respectively. Additionally, this reservoir contains SiO2 at 58.68 mg/L, Fe at 11.44 mg/L, K at 51.6 mg/L, Ca at 43.5 mg/L, and Mg at 58.94 mg/L (Ramadhan et al., 2013).

2.4 Balneology Scheme in General

The balneological process begins with the identification and utilization of mineral or hot water sources that have therapeutic potential. Once the source is found, the next stage is water extraction and processing. This process involves a series of methods to purify and optimize the mineral content of water, thereby maximizing its therapeutic benefits (Gianfaldoni et al., 2017). The treated water then enters the storage and distribution phases. This stage is crucial to ensuring water quality is maintained and consistently available for various therapeutic applications.

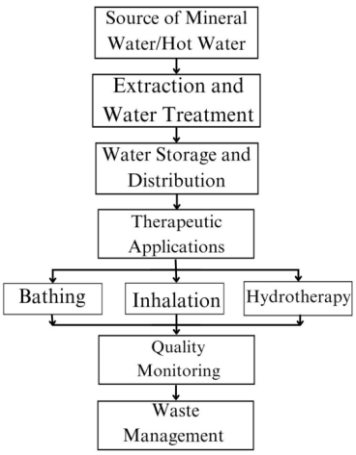

Figure 5: Balneology Scheme.

The therapeutic application of mineral water or hot water is divided into three main methods: soaking, inhalation, and hydrotherapy. Soaking involves immersing the body in mineral water, allowing the absorption of minerals through the skin, and providing a relaxing effect (Nasermoaddeli and Kagamimori, 2005). Inhalation uses mineral water vapor for respiratory therapy, potentially treating respiratory tract problems. Hydrotherapy includes a variety of techniques for using water for healing, including pressurized water massage and temperature contrast therapy. Each of these methods is designed to optimize the therapeutic benefits of mineral water, tailored to the specific needs of the patient or user.

After therapeutic application, the balneological process continues with two important stages, namely quality monitoring and waste management. Quality monitoring is a vital step to ensure the consistent effectiveness and safety of the use of mineral water in therapy. This includes regular testing of mineral composition, pH, and other water quality parameters. The final stage, waste management, is a sustainable aspect of balneology. This process involves treating used water to minimize its environmental impact, including recycling or safe disposal. Thus, the balneological cycle not only focuses on health benefits but also pays attention to aspects of environmental sustainability, creating a holistic approach to the use of mineral water resources for health (Gutenbrunner et al., 2010).

3. METHODOLOGY

This research uses a descriptive research approach to provide an actual picture of the geothermal conditions, potentials, and challenges that will be researched and planned. According to Faridi et al. (2021) Descriptive research is research that aims to describe existing phenomena, namely natural phenomena or man-made phenomena, or which is used to analyze or describe the results of a subject, but is not intended to provide broader implications. The methods used in the preparation of this scientific work are literature studies from books, journals, and relevant articles.

Data collection in this research was conducted through literature studies. According to Danial and Warsiah (2009), literature study is a form of research conducted by researchers by collecting a number of books, magazines, or other sources of information relevant to the research problem and objectives. In this study, secondary data used was obtained from literature journals. Data analysis was carried out using qualitative methods, namely by categorizing the raw data obtained as needed, presenting data interpretation, and narrated data analysis in accordance with the topic of discussion. Then, conclusions are drawn based on the data that has been processed. This research will identify and analyze waste heat from the Dieng geothermal power plant, existing potential, and challenges to formulate appropriate solutions

4. RESULT AND DISCUSSION

4.1 Brine Waste Processing

The process of flowing hot water from geothermal production wells to balneological facilities is carried out using pipes. The pipes used must be strong against corrosion, high pressure and temperature, and salinity. According to Nogara & Zarrouk (2018), several types of materials help prevent corrosion, such as carbon steel, stainless steel, and other corrosion-resistant alloys (CRA) which contain iron, nickel, chromium, and molybdenum in varying amounts. The salinity of geothermal hot water is very high which causes scaling to occur. Scaling in pipes occurs due to the formation of deposits which can hinder the water distribution process, besides that scaling reduces thermal conductivity and all heat transfer coefficients (Baba and Ármannsson, 2006). The common scaling is

amorphous silica scale (SiO2) (Agustinus et al, 2018). The following is an example of an image of scaling occurring.

Figure 6: Amorphous Silica Scale on Re-injection Pipes (PT. Geodipa Energi, 2009).

It is necessary to prevent scaling from occurring in order to reduce obstacles to the hot water flow process. There are 3 methods studied to prevent scaling in pipes, below is an explanation of each method.

1. PAC (Poly Aluminium Chloride)
   Research from Syafri and Rosana (2018) on preventive techniques to minimize scaling in the Dieng geothermal area using PAC (Poly Aluminum Chloride) coagulant is considered effective. The optimum dose required is a PAC concentration of 10 ppm, pH conditions of 8, and the addition of a Polyamide flocculant concentration of 1 ppm. Mixing or stirring treatment can increase the effectiveness of preventing scaling because the added coagulants and flocculants can be homogeneous so they work optimally. Flocculant is polyelectrolyte such as Polyamide compounds which serves to accelerate the larger formation of the floc core. The floc-floc density becomes greater than the density of water so that the floc-floc will form a precipitate sludge. The rate of deposition takes place gradually through the settling hindered phase, transition phase, and compacting phase (Kawamura, 1991).

Figure 7: Comparison of the Effectiveness of Coagulant Types on Precipitation (Agustinus et al, 2018).

2. pH Modification
   pH modification system has been adopted as an alternative scale prevention method since 2003. The purpose of this method is to reduce the silica-scaling rate by adjusting brine pH with sulfuric acid. Concentrated H2SO4 is injected into the brine in Hatchobaru, Japan, and at pH 5-6, the silica scaling rate was reduced significantly (Kiyota and Uchiyama, 2011). Because most geothermal liquids have extremely large buffer capacity, even for a small decrease, a large amount of acid is required (Topçu et al., 2019). For the mitigation of amorphous silica and metal silicates, pH modification with concentrated sulphuric acid (H2SO4) has been used in the Mak-Ban (Bulalo, Philippines) geothermal field (Gallup, 2011). Moreover, H2SO4 application contributes to the reduction of hazardous hydrogen sulfide emission from geothermal power stations that produced hydrogen sulfide gas was converted to H2SO4 with the help of a sulfur-oxidizing bacteria Thiobacillus thioparus (Hirowatari, 1996). To reduce the scaling rate, the pH was modified to slightly lower, but it was difficult to lower the pH in terms of corrosion problems of equipment. Corrosion is a serious issue, particularly in the elbow part of the pipeline, when such inorganic acids are dosed in the system. Apart from that, the hazards of sulfuric acid are also a factor in considering the use of this method.
3. Carbon dioxide (CO2) Injection
   Moreover, CO2 injection is another approach to prevent metal silicate scaling. Topçu et al. (2019) injected CO2 gas into the TGPP with various flow rates, and the results emphasized that 20.6 m3 /s CO2 injections showed a better performance than 55 ppm formic acid injection, and less corrosion is observed in CO2 gas injection (Topçu et al., 2019). In this way, a sustainable route can be achieved in geothermal systems by capturing the released CO2 from the system and injecting it through the wells. As a new perspective on the pH modification and antiscalant application in geothermal systems, there is a patent

application for the usage of CO2 as an antiscalant (Baba et al., 2020). The need for high capital and complex machine systems are challenges in implementing CO2 injection.

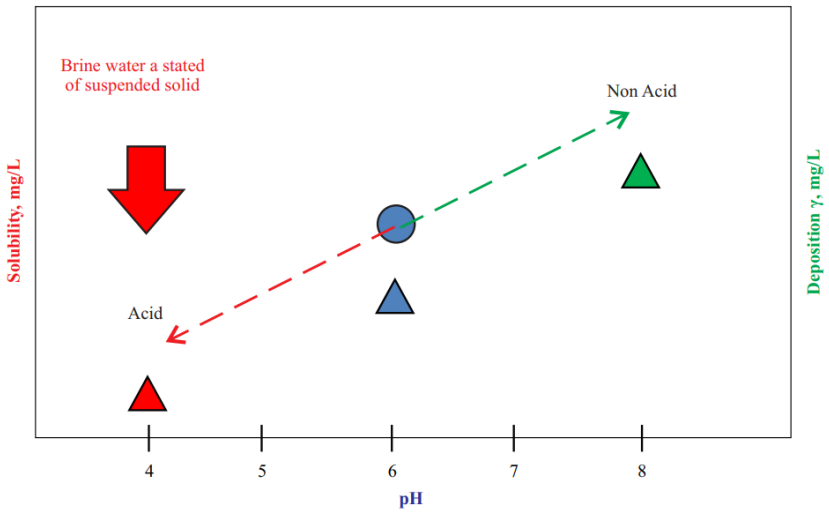

Figure 8: Graph of the Relationship between pH with Solubility and Deposition (Agustinus et al, 2018).

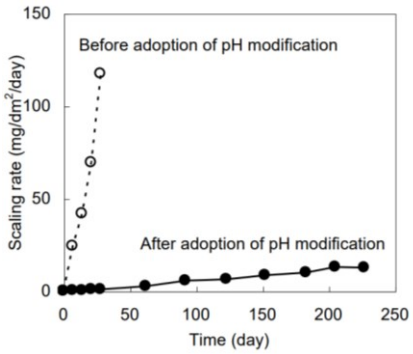

Figure 9: Effect of pH Modification on the Scaling Rate (Kiyota & Uchiyama, 2011).

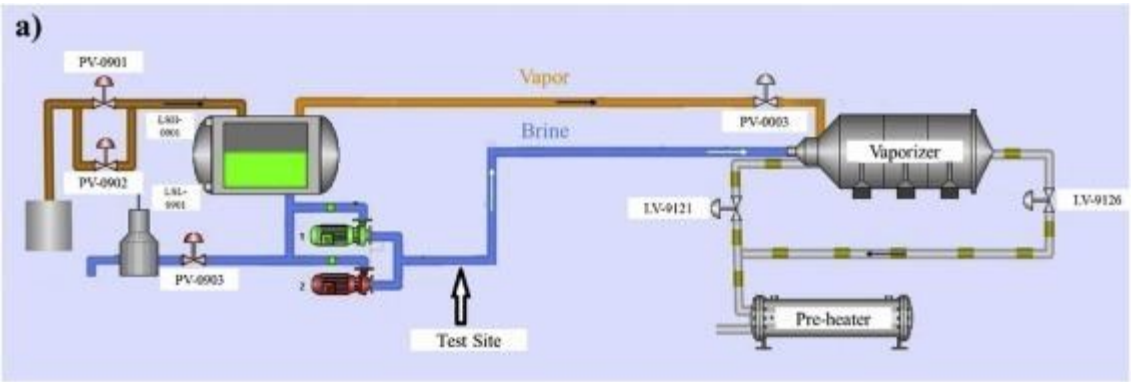

Figure 10: Scheme of The System CO2 Injection (Topcu et al, 2019).

Each method has its own advantages and disadvantages, so it needs to be considered in terms of economics, sustainability, and level of hazards. Below is a table of comparison levels between parameters and scaling prevention methods.

Of the three methods, taking into account the existing aspects, the recommended method to use is PAC coagulant, because it is seen from the side effects and costs required. As for the optimum conditions dose required is a PAC concentration of 10 ppm, pH conditions of 8, and the addition of a Polyamide flocculant concentration of 1 ppm.

Table 1: Comparison Levels Between Parameters and Scaling Prevention Methods.

Parameter	Methods of Scaling Prevention		
	PAC	pH Modification	CO2Injection
Complexity	Medium	Low	High
Corrosion Tendency	Low	High	Low
Environmental Hazard	Low	High	Low
Investment	Medium	Low	High
Sustainability	Medium	Medium	High

4.2 Balneology Scheme of Brine Waste

The brine temperature from the separator's outlet in Dieng geothermal reaches 180°C (Wisnu et al., 2020). In this temperature range, Dieng geothermal can be utilized through direct geothermal use, such as space heating or domestic hot water supply, as shown in the Lindal diagram (Chiasson, 2016). Therefore, the geothermal utilization of Dieng can be done by using a Geothermal Heat Pump (GHP) system.

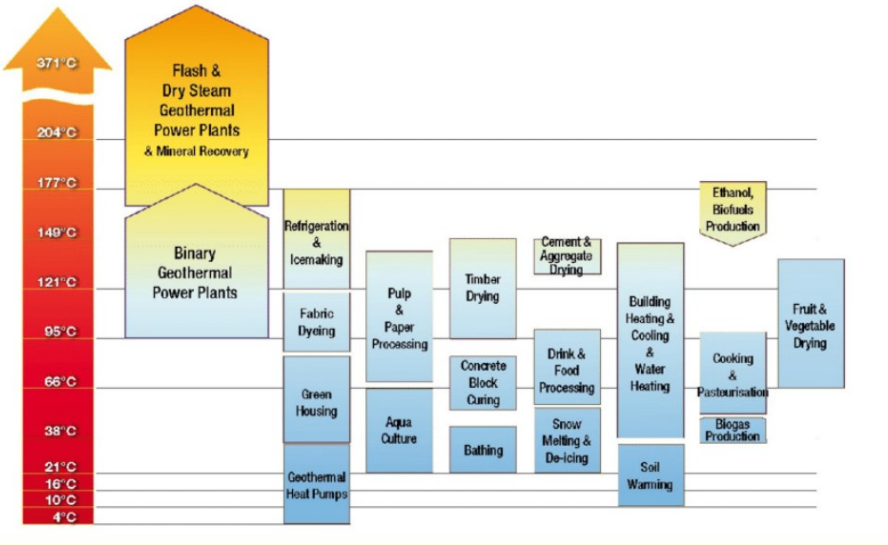

Figure 11: Lindal Diagram (Climo et al., 2015).

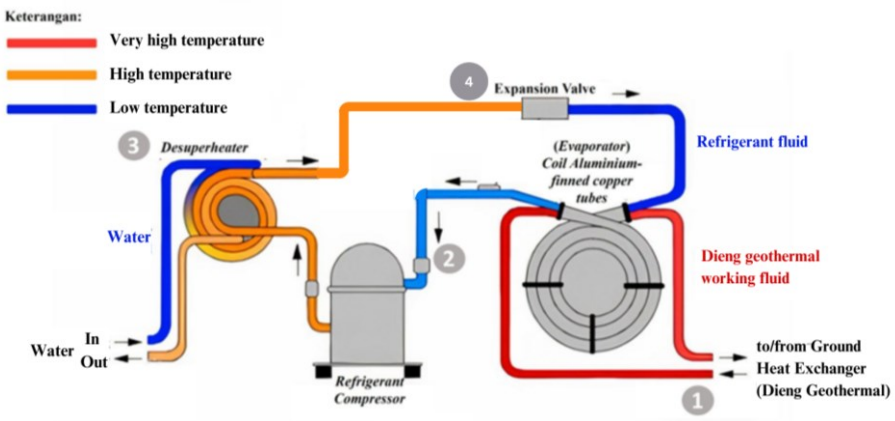

Figure 12: Geothermal Heat Pump (GHP) system in geothermal Dieng (Modified from Lund et al., 2004).

The heat exchange process in the Geothermal Heat Pump starts by transferring enthalpy from the Dieng geothermal working fluid to the heat exchanger working fluid in the evaporator. At this stage, the aluminum-finned copper tubes of the refrigerant heat exchanger act as a medium for heat exchange between the geothermal working fluid and the refrigerant (Chiasson, 2016).

Proper refrigerant selection in aluminum-finned copper tube coils is critical to ensure optimal performance and heat exchange efficiency in heat exchangers (Greco et al., 1997). Some common refrigerant types used in

geothermal heat pump applications are R-410A and R-407C (Kim et al., 2011). Factors considered in refrigerant selection include thermal efficiency, chemical stability, environmental impact, and safety.

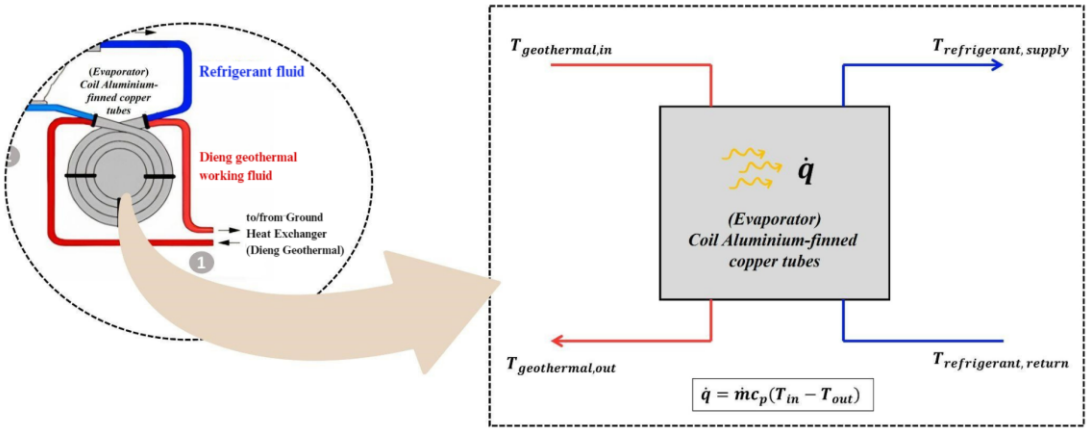

Figure 13: Displacement arrow of aluminum-finned copper tubes coil.

Table 2: Characteristics of refrigerant types R410A & R407C.

Refrigerant Type	Key Properties	Physical Properties	(GWP*)	Source
R410A (R32 and R125 hydrofluorocarbon (HFC) mixtures)	– Non-flammable – Non-toxic – Used in home air conditioning systems	– Critical Pressure: 4.92 MPa (713 psi) – Critical Temperature: 72.8°C (163.0°F) – Liquid Density: 1.21 kg/L	2.088	Kim, W., Kang, D., Lee, Y., & Jung, D. (2011)
R407C	– Non-flammable – Non-toxic – Used in home air conditioning systems	– Critical Pressure: 4.62 MPa (669 psi) – Critical Temperature: 87.3°C (189.1°F) – Liquid Density: 1.16 kg/L	1.774	Greco, A., Mastrullo, R., & Palombo, A. (1997)

*GWP (Global Warming Potential) is a number that measures the impact of these gases on global warming compared to CO_2 over a given period.

After the refrigerant working fluid undergoes vaporization in the evaporator, the resulting vapor enters the compressor to be increased in pressure and temperature. The compressor is responsible for increasing the pressure and temperature of the refrigerant to increase the heat exchange efficiency in the condenser. The high temperature of the compressed refrigerant is then flowed to the desuperheater to absorb excess heat from the refrigerant which is in a superheat condition after passing through the compressor (Hengel et al., 2016). Desuperheaters are effectively used as a heat source in domestic hot water supply by transferring excess heat from the refrigerant into domestic water. The hot water produced is around 50.43°C (Chahartaghi et al., 2019), which is utilized for hot springs or balneology.

Next, the refrigerant will enter the expansion valve. Inside the expansion valve, the temperature and pressure of the refrigerant will be lowered significantly. This process causes the refrigerant to experience a drastic drop in temperature and pressure, preparing it to return to the evaporator. After passing through the expansion valve, the refrigerant which is now in its initial low-pressure and low-temperature state, will then enter the evaporator to absorb heat from the geothermal fluid again. This process will continue to repeat in the cycle.

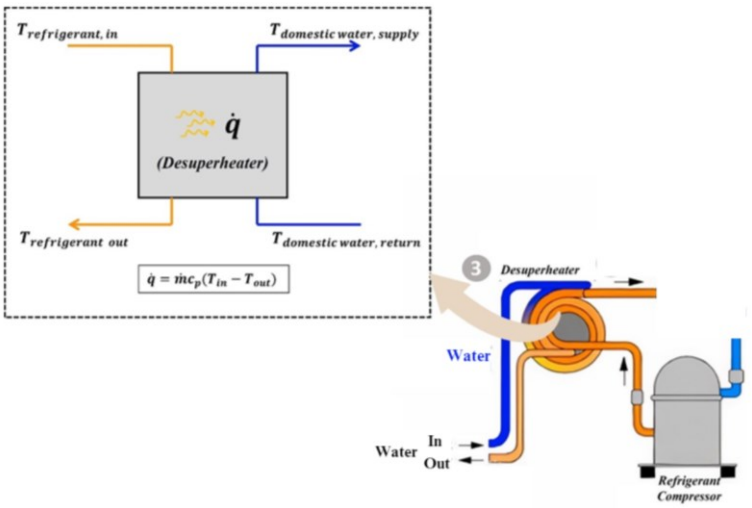

Figure 14: Heat transfer from Desuperheater.

4.3 Biological Analysis

Warm bath therapy through balneotherapy can cause dilation vessels blood, reducing viscosity blood and reduces tension resulting muscle improve blood circulation, so that can help lower blood pressure. This is also the best way and hassle-free side effects after use so it can be used as an alternative for reducing blood pressure (Fembi et al., 2019). The effects of balneotherapy generally appear as thermal, mechanical or chemical effects. Balneotherapy can be an alternative treatment method for treating health problems such as respiratory, cardiovascular, endocrine and neurological problems (Galvez et al., 2018). The thermal effect produced by the body is in the temperature range of 35-40 degrees Celsius. In this temperature range, blood flow in the body will increase, causing increased blood flow to the heart, lungs and brain (An et al., 2019). Hot water therapy in this temperature range can cause the body's rectal temperature to increase, namely to 38 degrees Celsius, and also cause the pulse rate to increase to 127 ± 18 beats/minute (Brunt et al., 2016).

4.4 Socio-economic Analysis

The application of brine waste in balneology in the Dieng area has complex social impacts, especially given the characteristics of the area as a tourist destination and geothermal site. One of the main problems that arises is the tension between the use of geothermal resources for electricity generation and their potential for balneological development. Local communities that have long relied on tourism as a source of income may feel threatened by changes in the economic landscape brought about by large-scale geothermal projects (Sukhyar et al., 2016). The problem that needs to be resolved concerns the use of brine waste for balneology in order to bridge this gap, create new jobs in the health and tourism sectors, and still utilize the potential of geothermal energy.

Another social aspect that needs to be considered is changes in land use patterns and community access to natural resources. The development of balneological facilities that utilize brine waste changes the dynamics of land ownership and management around geothermal sources (Yuniar et al., 2019). This problem has the potential to cause conflict if not managed well, especially if there is a perception that local communities are marginalized in the development process. A concrete case can be seen in complex negotiations between geothermal companies, regional governments, and local communities regarding land use rights and the sharing of economic benefits from balneological projects.

Social acceptance of geothermal projects is a key factor. Experience in various regions of Indonesia shows that community acceptance of geothermal projects often depends on perceptions regarding the direct benefits that can be felt by local communities (Nugroho, 2019). In Dieng, the integration of balneology in geothermal utilization could be a catalyst for increasing social acceptance. By demonstrating that brine waste can be used to create health and tourism facilities that benefit local communities, geothermal projects have the potential to gain wider support. However, the success of implementing brine waste-based balneology depends on transparent communication, involving the community in decision-making, and implementing a fair and sustainable benefit sharing program. If managed well, the development of brine waste-based balneology in Dieng can become a model for harmonization between the interests of the energy industry, tourism, health, and the aspirations of local communities (Oktavia et al., 2021).

A balneological review from an economic aspect in the Dieng area needs to consider the existence of several operating hot springs, such as D'Qiano Hot Spring Waterpark, Tegalsari, Sendang Sipandu, Legok Munggang, and Segar Asri. These facilities have become an integral part of Dieng's tourism landscape, attracting local visitors

as well as tourists from outside the area. The existence of hot springs shows that there is a market being formed for balneological services in the region, which is a positive indicator for the potential development of brine waste-based balneology (Oktavia et al., 2021).

In the context of balneological development using a brine waste system, economic analysis is crucial for assessing the feasibility and sustainability of the project. The initial investment costs to implement a brine waste processing system in balneological facilities can be quite substantial, including water treatment infrastructure, the construction of bathing facilities, and the development of supporting amenities (Lund, 2006). Utilizing brine waste, which is a by-product of geothermal power plants, can produce long-term cost efficiencies compared to conventional hot springs, which require natural hot water sources or artificial heating.

To assess the economic feasibility of this project, several economic indicators need to be considered. Break Even Point (BEP) is achieved within 3-5 years, depending on the scale of investment and level of tourist visits (Shortall et al., 2015). Levelized Cost of Energy (LCOE), to calculate the cost per visitor or per balneology session by considering the total cost over the life of the project divided by the number of visitors served (Yasukawa et al., 2018). The payback period is estimated to be between 5-7 years, considering the existing market potential and added value from the use of brine waste (Lund and Boyd, 2016). The project's internal rate of return (IRR) reaches 15-20%, making it attractive for investors (Lund, 2006). The benefit-cost ratio (BCR) is expected to be greater than 1, around 1.3–1.5, indicating that the economic benefits exceed the costs (Shortall et al., 2015).

The application of the brine waste system in balneology in Dieng not only has the potential to create long-term operational cost efficiencies, but the application of the brine waste system in balneology can open up opportunities for product differentiation. Balneological facilities that utilize brine waste can promote themselves as eco-friendly destinations, attracting market segments that care about the environment and health. Through this balneology, economic value will be increased through premium pricing and increased occupancy. In addition, integration with the geothermal energy sector can create economic synergies, where waste processing costs from power plants can be offset by income from balneological facilities. This holistic approach has the potential to create a business model that is more sustainable and resilient to fluctuations in the conventional tourism market (Oktavia et al., 2021).

5. CONCLUSION

The integration of geothermal heat pump technology with Dieng's geothermal energy source not only provides a clean and efficient solution for hot springs (balneology), but also has the potential to improve the overall health of Dieng communities and tourists and support sustainable tourism growth. With the active involvement of the younger generation in encouraging the utilization of clean and sustainable energy, Dieng can become a pioneer in maintaining a balance between economic growth and environmental preservation. By taking concrete action in utilizing Dieng's geothermal energy as a source of hot springs (balneology), we can realize easy access to clean energy to support sustainable tourism.

ABSTRACT

Climate change is a critical issue that has become a major global focus, with its primary cause being the accumulation of greenhouse gas emissions, particularly carbon dioxide (CO_2). Through the Kyoto Protocol and later the Paris Agreement, world leaders strive to anticipate the impacts of climate change through various methods. One of them is the implementation of renewable energy that emits none or very little CO2 to replace fossil fuels. Among these renewable energy sources, geothermal energy stands out due to its potential as a baseload energy source. The stability that geothermal energy provides is crucial to meet the global Net Zero Emission (NZE) target, as it would maintain a steady supply of electricity and ensure that energy demands are met without interruption. However, this requires key enablers, such as regulations and policies, to support the transition towards sustainable development.

A policy that economists consider highly effective is carbon pricing. As the name suggests, carbon pricing puts a price for carbon reduction to encourage industries and even countries to reduce their carbon emission. It comprises of two instruments, namely trading and non-trading instruments. By involving carbon trading as one of the instruments in the development of renewable energy, it can encourage the reduction of carbon emission, thus helping the world move closer to the NZE target.

Indonesia has an estimated total potential of 23 GW geothermal energy source, which amounts to 40% of the world's resource, making it a key player and a significant participant in the carbon trading mechanism. One of the major geothermal power plants in Indonesia is Patuha Unit-1, which is located in West Java and has the capacity of 55 MW. Operated by PT Geo Dipa Energi (Persero), it has been registered under the UNFCCC Clean Development Mechanism (CDM) since 2012. By implementing this mechanism, it is estimated that the project could reduce approximately 263,851 tCO_2e annually. Not only that, the project also estimated to experience an increase of IRR from 6.73% to 7.96%, making it essential for the viability of the project. This study analyses the multifaceted impact that CDM has on Patuha Unit-1 geothermal power plant project, including economic, environmental, and social aspects, while also contributing to the global decarbonisation goal.

1. INTRODUCTION

Since the 1960s, global temperature warming due to human activities has increased drastically. Compared to the pre-Industrial Revolution era, the global average temperature has risen by up to 1.1°C and is estimated to reach or exceed 1.5°C in the next 20 years, unless immediate actions towards reducing greenhouse gas (GHG) emissions are taken. With the expiration of the Kyoto Protocol at the end of 2020, global climate policy now refers to the Paris Agreement, which aims to prevent the global average temperature from increasing by more than 2°C and to limit the increase even further to 1.5°C. While the Kyoto Protocol bound developed countries to set joint commitments, the Paris Agreement has every country, including developing countries, determine their own commitments independently. These contributions are outlined in the Nationally Determined Contributions (NDCs).

Article 6 in the Paris Agreement is highlighted as embracing the business sector and leveraging the global market to support each country's government efforts to reduce carbon emissions. Through various cooperative approaches, the private sector is also encouraged to contribute to reducing carbon emissions and invest in green energy. One mechanism for achieving these ambitious goals is carbon pricing. Carbon pricing is an instrument that captures the external costs of GHG emissions—such as damage to crops and loss of property from man-made natural disaster—and ties them to their sources through a price, usually in the form of a price on the carbon dioxide (CO_2) emitted (World Bank, 2024). This carbon pricing assigns a price to GHG emissions that negatively impact

the environment. Economists believe that carbon pricing is one of the most efficient methods to encourage the reduction of GHG emissions. Several Scandinavian countries have implemented it since the 1990s; as of 2019, there are 56 carbon pricing policies implemented worldwide (Pérez & Rhode, 2020).

Indonesia has also strengthened their climate commitment by pledging to reduce their GHG emissions by 31.89% through own efforts and 43.20% with international assistance by 2030 under the Enhanced Nationally Determined Contribution (NDC). To achieve this, the government is undertaking several efforts in many sectors, including promoting renewable energy sources through policies and incentives. The government has set an ambitious target of generating 23% of its energy from renewable sources by 2025. The country itself is blessed with a significant geothermal resource of approximately 23.36 GW spread across 356 geothermal locations. However, it has only utilised less than 10% of its geothermal potential. In 2021, only 2.3% of Indonesia's primary energy mix came from the geothermal sector, while in 2023 only 13.1% of Indonesia's primary energy mix is from renewable energy.

The development of geothermal power plants ties into carbon pricing as it represents a shift towards low-carbon energy production. By investing in geothermal energy, a country reduces their GHG emissions, thereby lowering its carbon footprint. As a renewable and technically emission-free energy source, geothermal becomes more economically attractive under carbon pricing mechanisms. As the cost of carbon emissions rises, the cost-effectiveness of geothermal energy improves, encouraging further investment and development. This will help countries, like Indonesia, meet its emission reduction targets more efficiently while benefiting from the economic advantages provided by carbon pricing mechanism. This paper presents the importance of carbon pricing, in particular the carbon trading mechanism, to further the development of renewable energy, specifically geothermal sector in Indonesia, and the need for suitable policies to encourage this process by doing a case study on the sustainable impacts of the CDM on Patuha Unit-1 geothermal power plant project.

2. CARBON TRADING COMPONENTS

Looking back on the implementation of the Kyoto Protocol, it was often criticised for its perceived inequity, primarily due to its differentiated approach between developed and developing countries. Under which the obligation to reduce the emission were divided into two groups: Annex I countries, mainly developed nations required to reduce emissions, and Non-Annex countries, mainly developing nations that only had to report their emissions, but could also help reduce the emissions by cooperating with Annex I countries. A more progressive and ambitious emission reduction strategy necessitating equal contributions from all nations was seen as crucial. Thus, the Paris Agreement was established at the end of 2015, adopting a universal applicability approach. All participating countries committed to reducing their GHG emissions based on the principles of equity and common but differentiated responsibilities, as well as respective capabilities, considering their unique national circumstances. It was considered a turning point in international climate policy. The main goal is to keep the increase in global temperatures below 2°C above pre-Industrial Revolution levels and to limit the increase even further to 1.5°C. In contrast to the Kyoto Protocol, in Paris Agreement every country has the same opportunity to participate and is encouraged to submit their commitments for climate change efforts.

2.1 Carbon Project

Carbon project, an initiative designed to reduce, remove or avoid GHG emissions, with the goal of generating carbon credit, is one of the efforts to reduce the GHG emissions that is well connected to the carbon trading mechanism. One of the market-based mechanism under the Kyoto Protocol was CDM, and numerous carbon projects were developed under this mechanism. The CDM allows emission-reduction (or emission removal) projects in developing countries to earn certified emission reduction (CER) credits, each equivalent to one tonne of CO_2. These CERs can be traded and sold, and used by industrialized countries to meet a part of their emission reduction targets under the Kyoto Protocol (Kyoto Protocol Article 12). With the CDM market collapsing due to a combination of several factors, including oversupply of carbon credits, the economic downturn following the 2008 financial crisis, regulatory uncertainties, lack of new commitment under the Kyoto Protocol, resulted in credits from CDM projects prices dropped. Hence, with the emerging of voluntary market, which later strengthen by the adoption of the Paris Agreement in 2015, projects were shifting and operating under the voluntary market. Although carbon projects are operating under different market and mechanism, there are main requirements that those projects need to fulfil in order to be considered as eligible carbon projects. These requirements are set under the CDM and voluntary market standards which cover the principles, rules, requirements, as well as methodology to quantify the emission reduction for different kind of projects. To be eligible as carbon projects, a project must proof that it is reducing any of the GHG emission because of its activity. However, not all projects that reduced its emissions can be considered as a carbon project because it also needs to prove its additionality.

Carbon projects can be developed using different kind of technologies, including renewable energy, energy efficiency, methane avoidance, landfill gas, fuel switching, and other technologies that in principle will reduce

GHG emissions. Any carbon projects using technologies that prevent additional GHG emissions to enter the atmosphere by reducing the sources of emissions are categorised as carbon avoidance, which will become the main focus of this paper. Additionally, there are also carbon projects focusing on the nature-based solutions which will not be discussed in this paper.

2.1.1 Baseline Emissions, Project Emissions, Leakage and Emission Reduction

The concept of calculating emission reduction in a potential carbon project is determined by the value of the baseline emissions, project emissions, and leakage when applicable. A baseline emission is the GHG emissions that would occur in the baseline scenario meaning emissions that occur when the project activity is not implemented. For power generation projects, a baseline emission would be the existing emissions coming from the electricity network where a new renewable power plant will be connected to. This baseline emission is calculated based on the grid emission factor resulting from a mix of power plants that are supplying its electricity to that network.

A project emission is the GHG emissions that would occur as a result of the project activity. For power generation projects, a project emission comes from any activities under the overall project that emit the GHG, such as the use of steam in the geothermal project or the use of diesel fuel during power plant's shutdown period. Those emissions are to be monitored and included as project emissions.

A leakage from a carbon project is defined as GHG emission which occurs outside the project boundary, and which is measurable and attributable to the project activity. As an example, emissions from the transportation of diesel fuel to the project boundary can be considered as a leakage, as well as electricity consumption for a certain type of project. Determination of leakage for each type of project is different and is specific following the applicable methodology.

2.1.2 Additionality

Additionality is a crucial factor that determines whether a project is eligible to be considered as a carbon project or not. The definition of additionality under the CDM is the effect of the project activity to reduce anthropogenic GHG emissions below the level that would have occurred in the absence of the project activity. It implies that the project would not proceed without the CDM's intervention. To determine its additionality, a project must apply tools from UNFCCC that would demonstrate the additionality of a project. These tools will be able to show the extent to which carbon revenues bridge the viability gap for a project to be implemented and actually reduce GHG emissions. If a project can be implemented without the revenues or the push from carbon market or because it is a business-as-usual activity, then the project is not additional and is not eligible as carbon project. Three types of additionalities are recognised:

a) Project Additionality: This indicates that the project would likely not occur without CDM registration.
b) Environmental Additionality: This suggests that in the absence of the CDM project, a less GHG-friendly activity would likely be undertaken.
c) Technological Additionality: This requires that project activities involve the transfer of clean technologies that were previously unavailable in the project's region.

Thus, CDM project activities, and carbon projects in general, must demonstrate both additionality and contributions to sustainable development to be eligible. This eligibility check is conducted through the validation process which determine whether a proposed project meets the requirements to be registered as carbon project. Once a carbon project is registered and in operation, it must implement the monitoring plan that has been approved during the registration process. This monitoring activity will measure parameters that determine the actual reduction of GHG emission. This monitored emission reduction will then undergo a verification process to get it certified according to the standards that it is registered to. Only certified emission reductions will be able to be traded in the carbon market.

2.2 Carbon Trading

Pérez and Rhode (2020) noted that global CO_2 emissions have reached their highest level in 2017, with an increasing trend for the last 250 years and an average annual growth rate of 3%. Currently, China and the United States are the biggest polluter, followed by India and Russia (Figure 1). As a response, carbon pricing initiatives have emerged as vital tools for both the public and private sectors, as these assign a cost to carbon or GHG that negatively impacts the environment. By internalising the cost of carbon emissions, the societal burden is shifted to the polluters themselves, adhering to the polluter-pays principle. When polluters are made to pay for their emissions, they are discouraged from emitting as much, and the products they manufacture become relatively more expensive. This leads to reduced demand for their products and incentivises innovation to develop greener methods of providing goods and services. This rationale underscores the need for deliberate policy measures to price pollution. For the purpose of clarity, this paper will only focus on carbon trading instruments.

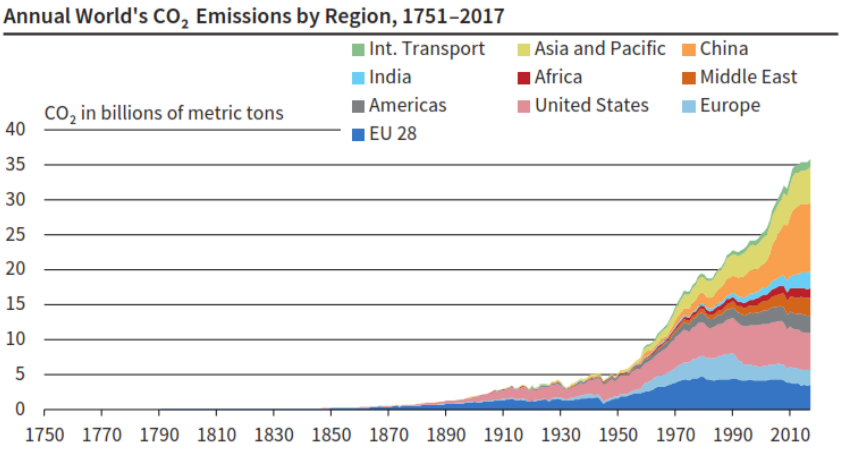

Figure 1: Annual world's CO_2 emissions by region (1751-2017). (Pérez & Rhode, 2020).

The carbon trading instrument, commonly known as cap-and-trade, involves trading certificates allocated in limited quantities in the carbon market. If the party generating carbon credits has a surplus of credits beyond what it needs, then it can sell the surplus on the market. On the other hand, if any party is lacking credits, then it can purchase from those with a surplus or from the market. This creates a carbon market situation determined by supply and demand, making the carbon price subject to market conditions. Generally, there are two types of trading instruments: emission trading schemes (ETS) and the crediting mechanism, which trade emission permits and carbon credits, respectively. Although this scheme mitigates overall carbon emissions and ensures flexibility, especially for businesses, the market-determined price implies higher uncertainty.

2.2.1 International Carbon Market

In general, the global carbon market is separated into two categories: regulatory market and voluntary market. The regulatory market was initiated under the Kyoto Protocol through three mechanisms, including the CDM, which will be highlighted in this paper. The voluntary market, born to capture those eligible carbon project that could not be implemented under CDM, was later strengthened by the Paris Agreement. The regulatory carbon market, i.e. CDM, is mandatory, involves host country government support and sometimes government-to-government (G2G) transactions. Annex I countries, that have ratified the Kyoto Protocol, have carbon credit quota per annum. Those that exceed their quota (credit deficit) have options to buy carbon credits from registered CDM projects in the developing countries. The voluntary carbon market, or offset emission, involves business-to-business (B2B) transactions and is generally supported by private entities with high attention to climate change. Awareness of their carbon footprint in their business activities drives the private sectors to participate in the market to reduce their emissions.

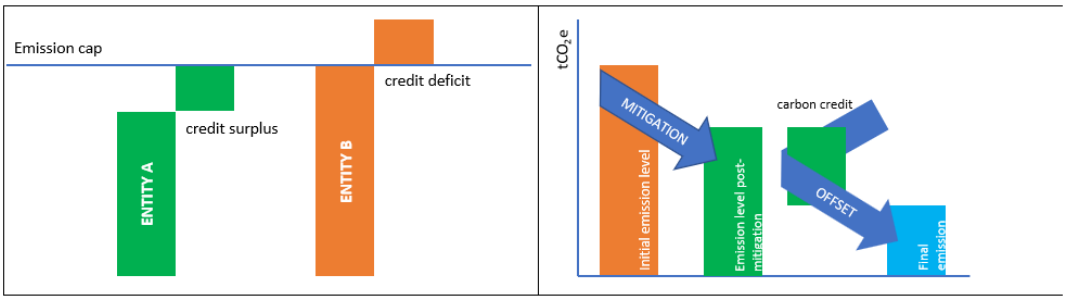

Figure 2: Regulatory and voluntary carbon schemes.
(Source: Fiscal Policy Agency of the Ministry of Finance of the Republic of Indonesia, 2021)

Based on IGES CDM Project Database (2024), as of February 2023, the majority of CDM projects globally in the pipeline are renewable energy projects, accounting for 68% of the total with the majority of this comes from wind and hydro power project. The total issued CERs up to the year 2020 is approximately 2,351 million tonnes of CO_2. Under Article 12 of the Kyoto Protocol, the CDM allows projects to earn Certified Emission Reduction (CER) credits, each equivalent to one ton of CO_2, which count towards meeting a country's Kyoto Protocol targets. As explained above, it is only limited to Annex I countries. In contrast, Article 6 of the Paris Agreement defines a carbon market driven by supply and demand for international cooperation and the exchange of emission reductions between countries. This allows all governments to engage in voluntary cooperation in implementing their NDCs. While similar to its predecessor, Article 6 introduces greater flexibility, enabling both businesses and countries to participate voluntarily in achieving their NDC targets, which enhances the potential for broader

engagement and innovation in carbon reduction efforts, making the Paris Agreement's carbon market a more inclusive and dynamic mechanism for addressing climate change.

Separately, UNDP Voluntary Carbon Market Report (2024) noted that an approximate of 352 million tCO_2e of volume have been issued from the voluntary carbon market in 2021. There are several prominent carbon standards which companies have used to engage in international carbon market transactions, including American Carbon Registry (ACR), Climate Action Reserve (CAR), Gold Standard (GS), Verified Carbon Standard (VCS), Global Carbon Council (GCC), Plan Vivo (PV), and Climate Forward (CF). VCS holds the largest share of carbon credits, followed by GS. Climate Focus (2023) noted that South Asia region holds the largest share in voluntary carbon market, followed by East and South Africa in terms of total projects registered (19%) and Latin America and the Carribean in terms of credits issued (19.3%). Southeast Asia and Developing Pacific only accounts for 6.2% of projects registered and 11.8% of credits issued.

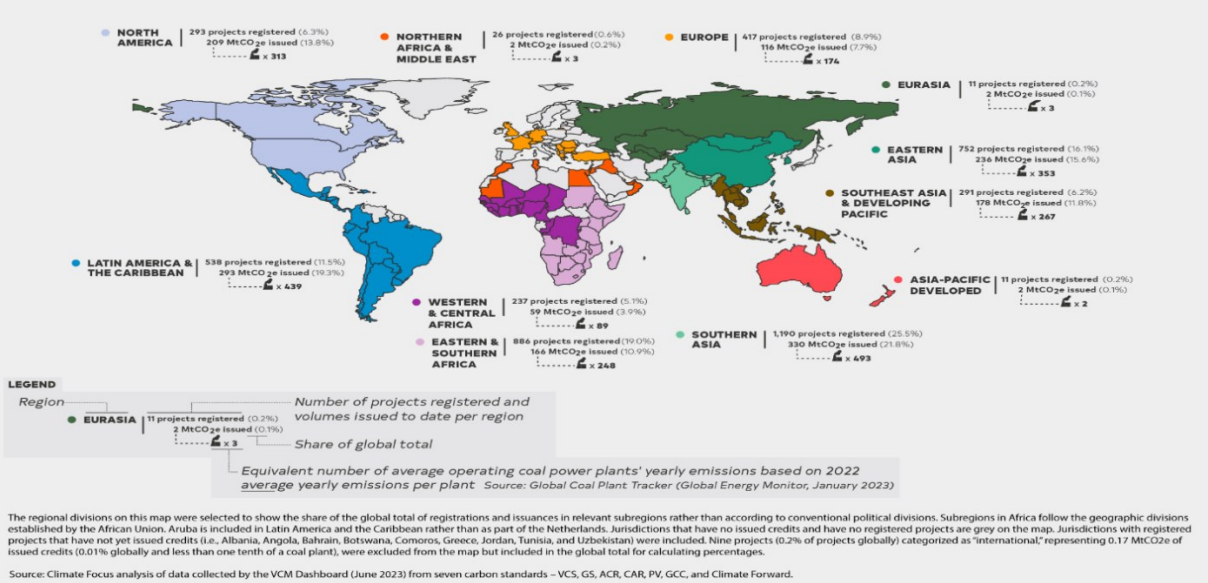

Figure 3: VCM credits issuance and registered projects. (UNDP Voluntary Carbon Market Report, 2024)

2.2.2 Indonesia Domestic Carbon Market

In 2021, the Government of Indonesia issued Presidential Regulation 98/2021 on Carbon Pricing, which requires businesses to reduce their emissions by adhering to an emission cap to meet the country's NDC targets. Only after achieving these targets businesses are allowed to monetize their credits in the market. This regulation represents a significant step in aligning Indonesia's climate action with economic value and international economic benefits. Consequently, the Government of Indonesia has identified carbon pricing as a key instrument to fulfill its GHG emission reduction commitments under the NDC while also incentivizing or commercializing the outcomes of these actions. Investors and businesses entering Indonesia's carbon market must understand the underlying principles of carbon pricing, which will be further clarified in the implementing regulations.

The Presidential Regulation explicitly delegates coordination authority across various ministerial sectors. Mulyana (2023) noted that through the Minister of Environment and Forestry (MoEF) Regulation 21/2022, the MoEF heads the general procedures for the implementation of carbon pricing. Delegation of authorities to different sectors has led to the establishment of a comprehensive carbon pricing regulatory framework. Multiple sector ministries, such as the Ministry of Energy and Mineral Resources (MEMR), have the authority to regulate carbon quota at the ministerial level. For instance, MEMR Regulation 16/2022 is crucial for Indonesia's energy sector as it sets the roadmap and cap for the power plant subsector.

Much like its international counterpart, the traded carbon credits in Indonesia's domestic carbon market are referred to as *Sertifikat Pengurangan Emisi Gas Rumah Kaca* (SPE GRK). All carbon projects are registered in the *Sistem Registri Nasional Pengendalian Perubahan Iklim* (SRN PPI), an Indonesian government-mandated carbon registry platform. SRN PPI serves as a comprehensive data policy tool for GHG emissions, accessible to the public, and containing detailed information on carbon projects, such as the account holder, the issued credit, the corresponding mitigation activity, and the credit status (whether retired or available).

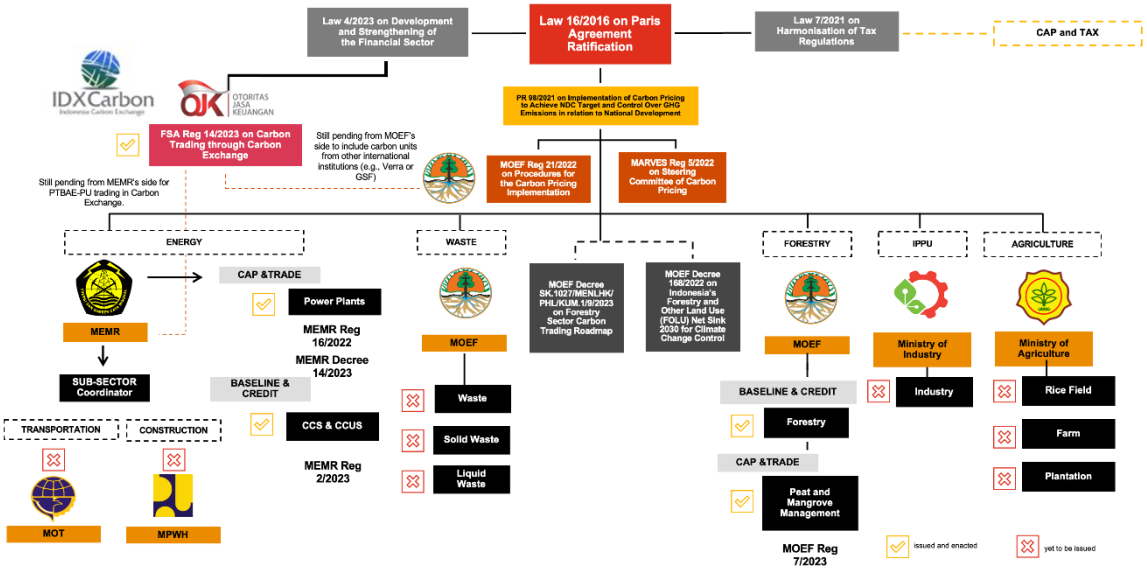

Figure 4: Current Indonesia's carbon pricing regulatory framework. (Mulyana, Fifiek and Indra Allen, 2023)

SRN PPI is anticipated to align with IDX Carbon, an Indonesian official carbon exchange, which was launched in September 2023 and operates under the supervision of the Financial Services Authority (Otoritas Jasa Keuangan, OJK). The Government of Indonesia currently uses IDX Carbon to focus on domestic carbon trading, prioritising its 2030 commitment. OJK Regulation 14/2023 underscores the necessity for traded carbon credits to be registered in SRN PPI beforehand. Although IDX Carbon appears to open opportunities for international carbon trading, this provision will be subject to further implementing regulations to be discussed with the MoEF.

2.3 Carbon Buyers and Sellers

The carbon market will not be alive if there is no buyers and sellers who conducted transactions in the market. In this market, sellers are project owners or project developers that initiate renewable energy projects which in and of itself generates carbon credits by reducing their GHG emissions. Buyers are businesses, organisations, even governments that wish to offset their carbon emissions by purchasing carbon credits from the sellers to meet their emission reduction target.

The Patuha Unit-1 project is developed by GDE and is registered under CDM with two project participants, GDE and Ecosecurities International Limited. Under the CDM, the buyers are Annex I countries, as it is within the Kyoto Protocol timeline, while the registered project participants are the sellers of CERs. Today, the market adopts the Paris Agreement in meeting their NDC and NZE plan, hence GDE upcoming GDE's units have the chance to be registered in the voluntary carbon market. Under the Paris Agreement, buyers are not limited to Annex I countries, making the carbon market driven by supply and demand, as well as the need for each country to meet their NDC targets. As a project owner, GDE already has PPAs for both Dieng and Patuha Geothermal Concession Areas, each with a planned 8 units to be developed. Therefore, GDE, with its significant potential still abundant in its geothermal areas to develop more geothermal power plants, has the chance to participate in the voluntary market.

Considering current carbon pricing regulations and policies in Indonesia, the carbon credits from these future projects should be traded within SRN PPI framework. Fossil-fuel based power plants or other companies aiming to offset their carbon emissions should be able to purchase these newly issued credits. Looking at the bigger picture of Indonesia's carbon policy, it is shown that international carbon market has proven significant demand for carbon credits. Hence it would be an opportunity for all the stakeholders in Indonesia to participate and collaborate with the international carbon market as it could leverage the country's targets to meet NDC, while at the same time invite investments to come into the country.

3. GEOTHERMAL POTENTIAL FOR EMISSION REDUCTION IN INDONESIA

Located in the Pacific Ring of Fire among three active tectonic plates, Indonesia boasts approximately 127 active volcanoes, resulting in a substantial geothermal resource potential of about 23.36 GW and making it one of the top three countries with the largest geothermal reserve alongside the United States and Japan (JFS Japan, n.d.). The capacity factor of geothermal power plants can reach 90% per year, allowing them to serve as a reliable baseload in electricity systems with higher capacity utilisation compared to other energy sources. Unlike wind

and solar energy, geothermal energy's productivity is relatively unaffected by climate change, offering a consistent and stable energy supply throughout the year. The utilisation of geothermal energy can significantly reduce dependence on fossil fuels. Guttiérez-Negrin (2024) noted a global increase in geothermal installed capacity from 15,414 MW to 16,318 MW between 2018 and 2021, with Indonesia contributing 246 MW to this growth. In 2020-2021, Indonesia held the second highest geothermal installed capacity globally, as shown in Figure 5.

Table 1: Geothermal Resources in Indonesia. (Geological Agency, 2021)

No.	Island	Points of Location	Resources (MW)					Total Installed Capacity
			Speculative	Hypothetic	Reserves			
					Probable	Possible	Proven	
1	Sumatera	101	2,167	1,567	3,624	976	1,126.4	949.75
2	Java	75	1,259	1,191	3,260	377	1,820	1,253.8
3	Bali	6	70	21	104	110	30	0
4	Nusa Tenggara	34	215	146	783	121	12.5	19.08
5	Kalimantan	14	151	18	6	0	0	0
6	Sulawesi	90	1,352	342	989	180	120	120
7	Maluku	33	560	91	485	6	2	0
8	Papua	3	75	0	0	0	0	0
Total Location		**356**						
Subtotal Potential Resource			**5,849**	**3,376**	**14,131.9**			
Total Potential Resource			**23,356.9**					

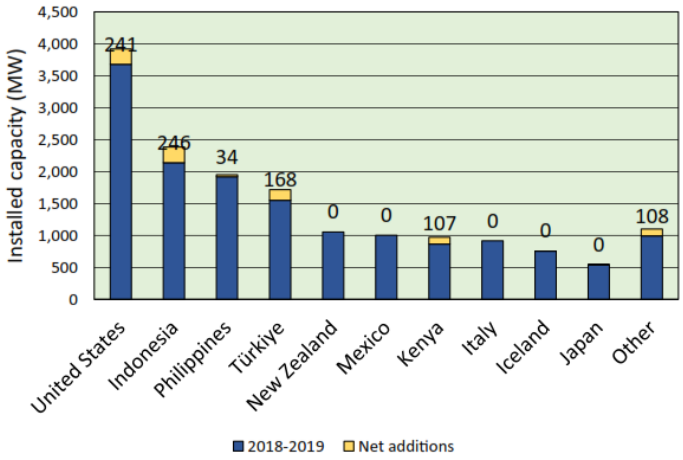

Figure 5: Top ten countries with the highest geothermal installed capacity in 2020-2021, and net additions in MW over the last 3 years. (Guttiérez-Negrin, 2024)

Indonesia's geothermal industry has a long history, with the first major project established in Kamojang, West Java, in 1983. The largest individual field by installed capacity is Gunung Salak in West Java, with 376.8 MW across six single-flash power plants, followed by Sarulla in North Sumatra, with 330 MW in three binary ORC power plants. These fields are operated by JOCC Star Energy Geothermal Salak, Ltd., and JOCC Sarulla Operations Ltd., respectively (Susmanto et al., 2023). As of 2022, there are 18 operational geothermal fields in Indonesia, including Dieng and Patuha, each with a net capacity of 55 MW, owned by PT Geo Dipa Energi (Persero) (GDE).

3.1 The Challenges to Indonesia's Geothermal Development

The Government of Indonesia's energy strategy focuses on diversification, environmental sustainability, and maximising the use of domestic energy resources. The National Energy Policy (Kebijakan Energi Nasional, KEN) 2014 targets a primary energy mix of 23% new and renewable energy (NRE), with 3% from geothermal, by 2025. Indonesia is also committed to achieving NZE by 2060 or earlier. Geothermal power is pivotal in reaching these targets, given Indonesia's status as the country with the largest potential geothermal capacity. However, the country currently utilises only about 9.81% of its geothermal potential. Development of geothermal power projects is prioritised in both the State-Owned Electricity Company's (PLN) Electricity Business Plan (Rencana Usaha Penyediaan Tenaga Listrik, RUPTL) and the Government's National Energy General Plan (Rencana Umum Energi Nasional, RUEN) to meet Indonesia's NRE target. However, the overall pace of development has been slow.

Despite being commercially viable, geothermal power projects in Indonesia face significant sector-specific challenges that deter investments. Setiawan (2014) categorises these challenges into upstream side problems, downstream side problems, and supporting side problems.

3.1.1 Upstream Side Problems

The lack of information on available reserves leads to investor uncertainty, which results in high upfront capital requirements. The risk of exploration failure further hinders project bankability and complicates financing efforts. Additionally, geothermal sites sometimes overlap with conservation and protected forests, posing environmental and regulatory challenges.

3.1.2 Downstream Side Problems

Inadequate incentives and pricing mechanisms fail to reflect the environmental benefits of geothermal technology and do not provide investors with a return commensurate with the higher risks associated with developing green geothermal fields. The presence of only one buyer in the geothermal market weakens the sellers' bargaining position, further deterring investment.

3.1.3 Supporting Side Problems

Indonesia's complex bureaucracy poses significant obstacles to realising the country's ambitious climate targets, with too many business permits as well as inconsistent rules and regulations. This bureaucratic complexity indicates a lack of commitment and awareness among consumers and society about renewable energy development.

Given the slow pace of geothermal power project development and the sector-specific challenges, policymakers in Indonesia should emphasise the importance of carbon trading as a strategic tool to realise the country's domestic and international climate and renewable energy goals. By prioritising carbon trading, Indonesia can leverage market mechanisms to attract investment in geothermal energy, stimulate innovation in green technologies, and ensure a cost-efficient and transparent path to achieve its NDC and NZE targets by 2060.

3.2 Analysis of Carbon Trading on Geothermal Projects in Indonesia

As explained previously, an eligible carbon project must meet additionality requirements as well as proving its sustainable impact. Thus, engaging a geothermal project as carbon project in carbon trading mechanism can significantly enhance the financial viability of geothermal projects in Indonesia. It should be noted that geothermal projects are heavily dependent on government support, such as subsidies or tax incentives, to make it bankable. By incentivising geothermal projects with carbon trading, it not only boosts the economic attractiveness of renewable energy projects as a whole, but also drives higher demand for geothermal energy. Companies will strive to meet emission reduction targets; increased demand can lead to more favorable power purchase agreements (PPAs) or feed-in tariffs for geothermal electricity, which will provide a stable revenue stream for developers (Indonesia Carbon Trading Handbook, 2022). This should also be supported by a solid policy from the government of Indonesia, as transparent carbon market further enhances market efficiency and competitiveness (Saputra et al., 2022).

Pongtuluran et al. (2024) conducted a hypothetical case study to analyse the effect of carbon trading in a geothermal project by comparing two scenarios: one without carbon trading (Baseline Case) and one with carbon trading (Optimised Case). The Baseline Case relies solely on electricity sales to PLN, while the Optimised Case includes revenue from both electricity sales and carbon trading. The study, focusing on Project ABC located on Java island with a capacity of 55 MW and a capital cost of USD 243 million, employs standard geothermal power plant parameters, such as a 90% capacity factor and major plant overhauls every five years. The economic feasibility assessment compares project revenue, net present value (NPV), and internal rate of return (IRR) between the two scenarios, as illustrated in Figure 6.

In the assessment for a 30-year operational period, the Baseline Scenario generates cumulative revenue of USD 1.088 million but results in a negative NPV of USD -31 million for the project and USD -43 million for equity. With a weighted average cost of capital (WACC) of 7.73% and a cost of equity of 13.5%, the project's IRR of 6.24% and equity's IRR of 6.47% fall short. Conversely, the Optimised Scenario yields greater cumulative revenue of USD 1.122 million, and while the NPV and IRR remain unfavorable, they show improvement. The project's NPV is USD -24 million and the equity's NPV is USD -40 million, with a project IRR of 6.59% and an equity IRR of 7%. Although both still below the desired rate, the hypothetical case shows the benefits of carbon trading inclusion in a geothermal project by enhancing the project's financial performance, demonstrating increased revenue as well as improved NPV and IRR compared to the Baseline Scenario.

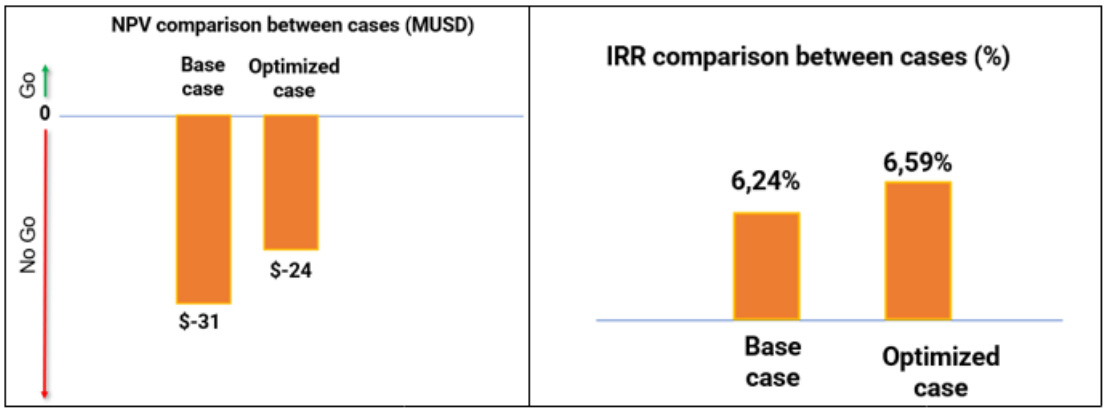

Figure 6: NPV and IRR Projections of Baseline Scenario and Optimised Scenario of Project ABC. (Pongtuluran, 2024)

4. SUSTAINABLE IMPACT OF CDM ON PATUHA UNIT-1 GEOTHERMAL PROJECT

Patuha Unit-1 is one of the major geothermal power plants in Indonesia, having its 55 MW capacity in operation and generating electricity for the Jawa-Madura-Bali (JAMALI) grid, which serves as the biggest grid in Indonesia. This power plant activity has been registered under the CDM since 2012 using CDM methodology ACM0002 of Consolidated Baseline Methodology for Grid-Connected Electricity Generation from Renewable Sources, version 12.2. The activity has proven its additionality by showing that the inclusion of carbon mechanism could increase the Patuha Unit-1's IRR from 6.73% to 7.96% and bridging the viability gap of the project at the time of decision making. During those times, its registration as a CDM project also played a role in the push for the project to be realised and in operation starting September 2014.

In its CDM registered documents, the power plant was expected to reduce an estimate amount of 263,851 tCO_2e annually, taking into account the latest grid emission factor at the time of project registration. The power plant's actual emission reduction certified under CDM has not yet been determined as the power plant is still undergoing verification process when this paper is written. However, the sustainable impact of the power plant can be acknowledged.

Since its start of operation in September 2014, the power plant has supplied an average of annual electricity generation of 446.43 GWh to the JAMALI grid. Hence, it supports the reduction of GHG emissions in the grid. Taking the latest grid emission factor value issued by the Ministry of Energy and Mineral Resources of 0.83 tCO_2e/MWh for JAMALI, those generations can be estimated to quantify as a gross reduction of 370,536 tCO_2e GHG emissions per year. Although the net value of the reduction will be lower as it needs to consider the detailed annual steam production and diesel fuel usage during any shutdown period in the power plant, this reduction of over 0.3 million tCO_2e of GHG per year is equivalent to the amount of CO_2 emissions absorbed around by 463 hectares of Indonesia's average primary dryland forest. This clearly illustrates how the power plant is contributing directly to the environment with positive impact and help the country to achieve its net zero emission and NDC target.

In addition to its support related to SDG 13 for climate action through its direct effort in reducing GHG emissions, the power plant has also been providing positive impact for the communities in four villages who live around its location. The impact includes environmental impact, social impact, and economic impact.

In the environmental aspect, the power plant always prioritised environmental sustainability so that the ongoing operational processes do not disturb the surrounding environment. The power plant also minimises any potential disturbances that may arise, such as equipment noise/noise inside the power plant and wells, by installing silencer walls, planting trees around the guardrail and using rock mufflers. They also collaborate with the communities around the operational area to carry out conservation programs so that the communities improve their awareness of environmental sustainability concerns. The conservation programme includes flora and fauna species where they conserve land orchids (*Goodyera viridiflora* and *Anoectochilus spp*), Javanese primate Surili (*Presbytis comata*) and Lutung *(Trachypithecus auratus*).

To ensure that the power plant operation also gives positive social impacts to the community, the power plant implements many programmes, such as the scholarship programme for bright young students, book donations to improve literacy and reading interest in the village communities, and vocational training to improve skills. During the COVID-19 pandemic period, the power plant supported the local communities in the health and economic sector by providing training for healthcare for collaborative COVID-19 treatment and management, improving

communities' awareness on sanitation and health issues, and providing staple food package to ensure food security for the communities.

Through construction or investment of infrastructure in the surrounding area where Patuha Unit-1 is operated, the power plant provides indirect economic impacts to the communities. One example is the program to improve the electricity network as the villages are in the remote area that is very far from the main road and thus not yet well connected to the grid. With more reliable electricity, children in the villages can study well during the night and the birth process that happens during nighttime in the villages can be done with ease. Further example is the collaboration of the power plant with Village-Owned Enterprise *(BUMDes)* by providing training and education to improve local workforce's competency and expertise that help their income source.

Ideally, when a carbon project's emissions reduction has been certified, this certified emission reduction can be sold in the carbon market and thus adding revenue to the power plant. This additional revenue will help the power plant operational cost and can also improve the environmental, social and economic impact that the power plant has been giving to the communities. Currently, the power plant is undergoing a verification process with one of its aims is to be able to take some benefit of the certified emission reduction sales to the community by ensuring continuous improved impact to the community.

5. CONCLUSION

With the Global CO_2 emissions showing an increasing trend overtime, i.e. average annual growth rate of 3%, urgent action and intensified efforts to tackle the climate change impact are required. The world now strives to limit the rise of global average temperature to 1.5°C, which means immediate action is crucial. The transition from the Kyoto Protocol to the Paris Agreement underscores the collective responsibility of all nations to mitigate climate change through independently determined commitments, more commonly known as NDC. It marked a significant shift in international climate policy, emphasising universal participation and equal contributions from all nations to mitigate GHG emissions.

Furthermore, the carbon trading mechanism as one of carbon pricing instruments plays an important role, especially in Indonesia, to reach the country's NDC. It is a flexible, market-drive solution for reducing emissions, with both regulatory and voluntary markets playing pivotal roles. A well-established carbon trading mechanism ensure transparency and provide options for buyers, which enhances the appeal of carbon projects that employ various technologies to reduce GHG emissions. Indonesia's domestic carbon market, regulated by Presidential Regulation 98/2021, encourages businesses to meet the country's NDC target while enables the monetisation of carbon credits. Compared to other Asian countries, Indonesia is ahead in their carbon market initiatives. Many renewable energy project developers are eager to learn more about Indonesia's domestic carbon market process, as well as available options for buyers and sellers. This clarity can help carbon credits from Indonesia to be traded internationally and domestically through the approved mechanisms by the government.

Being one of the top three countries with the highest geothermal potential and installed capacity, Indonesia would be amiss to not utilise their geothermal resources to help the development of renewable energy and to support the country's decarbonization goals. Geothermal's characteristics of high capacity factor, reliability, and the fact that it is not affected by climate variability makes it a consistent and a key player in reducing dependence on fossil fuels. However, geothermal is not without its challenges; its development has long been plagued with high upfront costs, regulatory hurdles, and inadequate incentives. Carbon trading has the potential to enhance the economic feasibility and viability of geothermal projects by providing additional revenue through carbon credits sales. It also encourages investment and innovation, which in turn supports Indonesia's NDC and NZE targets. A hypothetical geothermal project case study simulated by Pongtuluran et al. (2024) shows that the addition of carbon credit sales increased the project's revenue, IRR, and NPV, as compared to scenario without carbon credit sales.

As one of Indonesia's major geothermal power plants, Patuha Unit-1, with a capacity of 55 MW, has been pivotal in reducing GHG emissions and supporting the JAMALI grid. Registered under the CDM since 2012, it demonstrated additionality by increasing its IRR from 6.73% to 7.96%, making the project viable. The power plant, operational since September 2014, has supplied an average of 446.43 GWh annually, reducing an estimated 370,536 tCO_2e GHG emissions per year. This impact is equivalent to CO_2 absorption by 463 hectares of primary dryland forest and it aids Indonesia's NDC and NZE targets. The project also fulfils SDG 13 for climate action through its direct effort in reducing GHG emissions. The additional revenue that the power plant receives from carbon trading will help the operational cost as well as improve the welfare of its environment and social landscape. Since operating, the plant has positively impacted local communities, particularly the four nearby villages. It improves the energy mix in the JAMALI grid (SDG 7), provides training to improve local workforce's

competency, and scholarships for students in the village communities (SDG 4). It also collaborates with the communities around the operational area to carry out conservation programs for local flora and fauna (SDG 15) (Department of Economic and Social Affairs, United Nations, 2024).

As such, while Indonesia embraces the change towards a sustainable future, there is still more work that can be done to encourage more participants, particularly in the carbon market. Indonesia still has rooms of improvements, including enhancing the carbon market framework, providing more clarity and transparency on the implementation of carbon market, as well as participating and collaborating with the international carbon market. More international collaborations would speed up the country's road to net zero emission and fulfill their NDC goals.

Keywords: Geothermal Brine Utilization, Heating System, Internet of Things, Energy Efficiency, Tourism Facilities

ABSTRACT

Popularly referred to as the Land Above the Clouds, Dieng is a highland in Central Java, Indonesia, that offers stunning natural beauty and rich culture. In recent years, Dieng has developed into one of Indonesia's most popular tourist destinations, attracting thousands of domestic and foreign tourists each year. This success is not only caused by its natural and cultural beauty, but is also supported by developing accessibility, improved tourism services, and comfortable accommodation facilities. In providing accommodation facilities, spaces and water heating for tourists become indispensable. Apart from its tourism aspects, Dieng also possesses electricity-producing geothermal fields (power plants) in Central Java. However, the power plant only utilizes steam-phase geothermal fluids, resulting in waste in the form of liquid-phase geothermal fluids (brine). The brine has tremendous potential as its temperature reaches 180°C. This indicates potential utilization of geothermal brine to provide comfortable accommodation facilities, especially for space and water heating. In the proposed scenario, the brine from the separator outlet will be transmitted through pipes to the tourism areas. This energy will be utilized for the space heating and water heating systems in villas. Based on analysis, assuming a heat loss of 5°C per kilometer on the pipes and a brine flow rate of 0.5 kg/s, the energy carried by this brine reaches 304.5 kW. The brine will flow through an aluminum-finned copper tube coil to transfer heat to the refrigerant. Subsequently, the refrigerant will pass through a compressor to increase its pressure and temperature; thus, transforming the liquid phase of the refrigerant into a superheated phase. This superheated phase of the refrigerant will be utilized for water heating through a desuperheater and for space heating through a condenser. In the space heating mechanism, cold air from outside will be drawn into the space by a blower fan, making direct contact with the condenser. Consequently, the heat from the refrigerant in the condenser will be transferred to the air, producing warm air suitable for space heating in the villas. To maximize energy usage and efficiency in space heating, a SMART heating system is proposed. The SMART heating system integrates the concept of IoT (Internet of Things) to carry out automatic control and monitoring of space and water heating systems. The system utilizes a temperature sensor for data acquisition of space conditions. Then, the control unit reads the data for processing. If the control unit detects the space temperature is below 20°C, it activates a reversing valve to heat the refrigerant with brine. Afterwards, the control unit activates the blower fan to warm the space. The SMART heating system regulates the opening of valves, as well as the performance of the blower so that the space temperature is ideal (20-22°C). Besides that, the water-heating scenario operates as the user's instruction. The hot water is stored in the storage tank for supply. The embedded IoT within the SMART heating system enables a more efficient energy management process, reduces greenhouse gas output from refrigerants, and reduces operational expenses.

1. INTRODUCTION

Dieng, a popular tourist spot situated in Central Java, Indonesia, has garnered favor among both domestic and international travelers. The breathtaking natural landscapes, vibrant cultural heritage, and diverse array of attractions have solidified Dieng's status as one of the top tourist destinations. The Dieng Plateau stands out as one of the main draws, renowned for its striking mountain vistas and refreshing climate, providing a distinct contrast to the typical tropical setting found in most parts of Indonesia. Additionally, sites such as the active Sikidang Crater offer visitors a unique opportunity to witness geothermal phenomena firsthand. Dieng has not only natural and cultural charm, but it is also enhancing its tourist amenities, such as accommodation and infrastructure, to enhance the overall tourist experience. These initiatives have effectively boosted the annual tourist footfall. Data from the Central Java Tourism Office shows that the number of tourist visits to Dieng increases consistently every year. In 2021, Dieng recorded more than 1.5 million tourist visits, and this number

continued to increase in subsequent years. In 2022, the number of visits increased to around 1.8 million tourists, and it is estimated that in 2023, visits will reach more than 2 million tourists.

Travelers who visit Dieng often seek comfort, particularly due to the cold temperature in the area. The use of geothermal energy for room and water heaters can offer additional comfort for tourists. Dieng is known for its significant geothermal potential and the utilization of geothermal steam phase for electricity generation. This process results in the production of liquid phase geothermal fluid (brine) with a temperature of up to 180°C. This brine holds great potential as an alternative energy source, particularly for providing comfortable accommodation facilities, including heating rooms and water in lodgings. The incorporation of brine for both room heating and water heating purposes has the potential to enhance the comfort of tourists while simultaneously decreasing reliance on environmentally harmful fossil energy sources. A research study focusing on the resource consumption patterns of guests residing in self-contained B&B accommodations was conducted. Data was gathered through a smart metering system spanning across four different seasons. The study revealed that the adoption of renewable energy sources, alterations in guest behavior, and emphasis on environmental preservation can significantly enhance resource utilization efficiency. Guests who were provided with sustainability guidance and information managed to achieve savings of 27% in electricity consumption, 22% in gas consumption, 22% in water usage, and 10% in firewood consumption (Warren, 2018).The substantial growth in tourism awareness and the increasing preference for sustainable accommodations among tourists, which prioritize renewable energy, effective waste management, and eco-friendly facilities, presents a lucrative opportunity for utilizing brine for space and water heating. Additionally, it can enhance tourism activities by providing unique and attractive amenities for visitors.

2. FIELD OVERVIEW

2.1 Reservoir Characterization

The Dieng geothermal field is a 63 km2, liquid dominated reservoir geothermal field located in Central Java, approximately 80 kilometers to the northwest of the Special Province of Yogyakarta. Currently, the Dieng field is operated by PT. Geo Dipa Energi with a total installed capacity of 60 MW as of 2019, though a resource estimation by West JEC (2006) using numerical methods indicate that the resource size is 240 MW.

From a geological perspective, the Dieng field has three main prospect areas; Sikidang, Sileri, and Pakuwaja. These prospect areas are separated by low permeability and low temperature barriers, defined by a gravity high and a low conductivity. Thus, a barrier separates the Sileri sector and Sikidang sector in the north and the Pakuwaja sector in the southeast. This study focuses mainly on the Sileri sector as the heating lines mainly utilize brine from wellsite 28, 30, and 31 which are located in the Sileri sector. The geothermal system of the Sileri sector is expressed by the surface discharge in the form of fumarolic discharges in Mt. Sipandu and hot spring discharge in Bitingan and Sileri Crater. These discharges indicate the location of an upflow zone in the Sileri sector. Based on analysis conducted by Shalihin et al., 2022, these findings indicate a mature hydrothermal system.

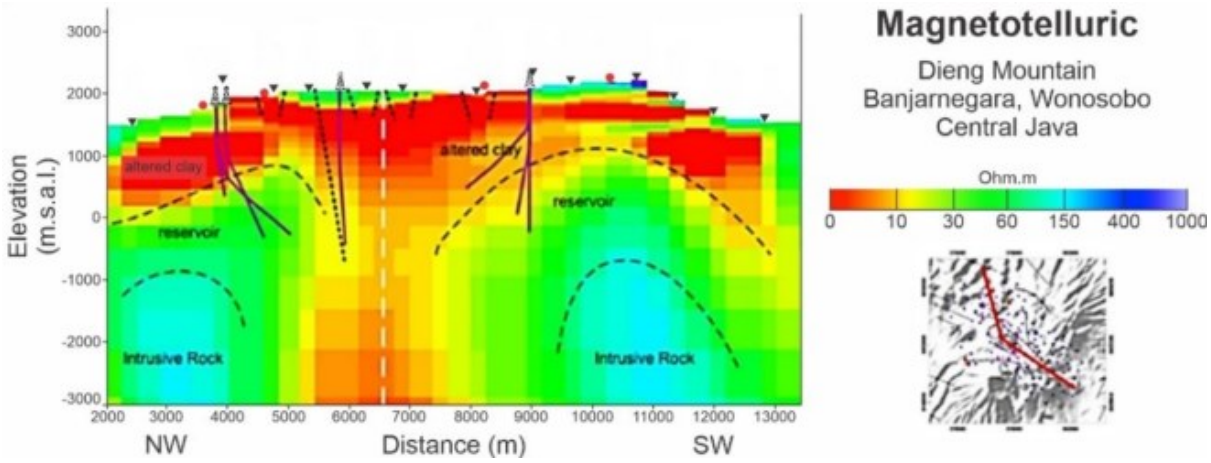

Figure 1: Cross-sectional 2D MT Inversion model of the Dieng Geothermal Field, Sileri sector is to the NW, Sikidang is to the SW. (PT. Geo Dipa Energi in MEMR, 2017)

2.2 Fluids Characterization

Sileri sector The subsurface hydrothermal mineral assemblage in the Sileri Crater consists of epidote, wairakite, calcite, quartz, albite, and clays (smectite, chlorite, illite), indicating the interactions of the rocks with near neutral pH-alkali chloride waters (Shalihin et al., 2022). The fluid originates from meteoric water which experiences slight mixing with magmatic fluid, water-rock interaction with sedimentary or meta-sedimentary rocks, and intensive boiling. Furthermore, the fluid is known to be two-phase (liquid-dominated) with neutral pH,

temperature ranging from 283 to 338 °C, low NCG (<1 wt%), enthalpy value 379.7 kJ/kg (Kencana et al., 2024; Pambudi et al., 2015). The elemental composition of geothermal fluid in Sileri Crater is as shown in Table 1.

Table 1: Fluid composition of Sileri Crater.

Element (ppm)	Sampling 1	Sampling 2
SiO2	1400	1145
Cl	21,499	25,400
SO4	-	-
Li	40	60
Na	8340	11,460
K	2520	3340
Mg	-	-
Ca	440	860

2.3 Silica Scaling Analysis

Silica scaling analysis is conducted to determine whether silica deposition will occur in the pipeline transmission for district heating. Silica scaling can affect the mass flow rate of the brine produced. The presence of silica scaling can be assessed by the Silica Saturation Index (SSI) of the geothermal fluid well. SSI can be calculated from the ratio of the saturated pressure of silica to the wellhead pressure according to equation (1).

$$SSI = \frac{P_{sat}(Silica)}{WHP} \quad (1)$$

According to data from PT Geo Dipa Energi, the saturated pressure values of silica and the wellhead pressure are as follows:

Table 2: SSI value at wellsite in Dieng area, PT Geo Dipa Energi (2023).

Wellsite	P_{sat}(Silica) (barg)	Well Head Pressure (barg)	SSI	Silica Scaling
HCE-29	24.9	45.6	0.54	Impossible
HCE-7B	22.2	23	0.96	Impossible
HCE-7C	27.5	33.4	0.82	Impossible
HCE-28A	20.	20	1	Saturated
HCE-28B	21.9	28	0.78	Impossible
HCE-30	23.4	34.1	0.68	Impossible
HCE-31	17	18.6	0.91	Impossible
HCE-10A	15.3	36.3	0.42	Impossible

SSI parameters can be used to estimate the amount of silica scaling with the following criteria, (Sofyan et al., 2021):

- If SSI > 1, the fluid is supersaturated and silica deposition is possible.
- If SSI = 1, the fluid is saturated.
- If SSI < 1, the fluid is undersaturated, so silica precipitation is impossible.

Based on Table 2, it can be concluded that there is a need to consider measures for handling potential silica scaling at wellsite HCE-28A before installing the pipeline transmission for district heating.

3. RESULTS AND DISCUSSION

3.1 Heat Transfer Analysis in the SMART Heating System

Heat transfer analysis is conducted using several mathematical models in accordance with thermodynamic processes. The parameter considered in the calculations is the temperature of the brine from the outlet separator. The parameters of the brine are shown in Table 3.

Based on Table 3, it can be seen that the brine temperature is 182 °C and it carries an enthalpy of 772.3 kJ/kg. The heat transfer analysis is conducted by considering three aspects: the pipe transmission system, the heat exchanger system, and the space heating system. The analysis evaluates the energy transfer efficiency and the energy losses that occur.

Table 3: Parameters of the brine from outlet separator of the single flash power plant (Pambudi et al., 2015).

Parameter	Value	Unit
Enthalpy h	772.3	kJ/kg
Entropy s	2.159	kJ/kg K
Pressure P	10.5	bar
Temperature T	182	$°C$
Mass flow $\dot{m}$	110.6	kg/s
Energy	77,077	kW
Exergy	16,143	kW

3.1.1 Pipeline Transmission System

Transmission line to distribute the brine will be installed in the Sikadang area, considering the large number of homestays in the area. The transmission pipeline will be connected to the brine line from then channeled to the homestay area and will be returned to the south brine pipeline to maintain the stability of the mass flow rate at the injection well.

Brine from the outlet separator will be channeled to the homestay facilities through a pipeline transmission system. The installation of the pipeline starts from wellpad #28 and leads to the brine channel to the pond and injection well. Figure 3 shows the pipeline route scheme for district heating in the Dieng tourist area.

Estimated length of the pipeline obtained from calculations using Google Maps is 2.86 km. From this length, it is necessary to consider the pressure drop produced to determine the heat loss that occurs due to the pipeline. To calculate the pressure drop produced by the pipeline transmission, equation (2) can be used.

$$\Delta P_f = 1.75\times10^{-4}\frac{fL\dot{m}^2}{\rho D^5} \quad (2)$$

$$f = \frac{0.25}{\left\{log\left[\frac{\epsilon}{3.7D}+\frac{5.74}{Re^{0.9}}\right]\right\}^2} \quad (3)$$

$$Re = \frac{4}{\pi}\frac{\dot{m}}{\mu D} \quad (4)$$

where L, $\dot{m}$, ρ, D, f, Re, ϵ, μ are the pipe length (ft), mass flow rate (lbm/s), brine density (lbm/ft3), inside diameter of pipe (in), friction factor given by the Swamee-Jain equation (3), Reynolds number, pipe roughness (ft), and absolute viscosity (lbm/ft s).

To consider the magnitude of the pressure drop generated in pipeline transmission, it is essential to select the pipe diameter and determine the desired mass flow rate. This selection utilizes commercial pipes made of ASTM A106 Gr B material. Analysis involves choosing pipe dimensions that result in the lowest pressure drop by adjusting the dependent variables: mass flow rate and inside pipe diameter. Figure 4 illustrates the analysis results of pipe diameter and brine mass flow rate's impact on pressure drop.

Based on Figure 4, it can be considered to choose a larger pipe diameter and reduce the mass flow rate of brine. Under optimal conditions, a pipe with an 80 cm diameter and a mass flow rate of 0.5 kg/s results in a pressure drop of 8×10^{-10} kPa, which corresponds to a temperature decrease as calculated in Table 4 and 5.

According to the calculations based on the change in brine enthalpy, the temperature drop due to pressure drop is not significant, with $\Delta T = 0.03°C$. Because of this minimal temperature drop, the transmission pipe does not require insulation coating. Therefore, brine from the brine line at 182°C will enter the district heating transmission pipe with an estimated temperature of 181.97°C after covering 2.86 km. Alternatively, we can estimate it to be 181°C, considering the thermal conductivity of the pipe which can cause heat loss.

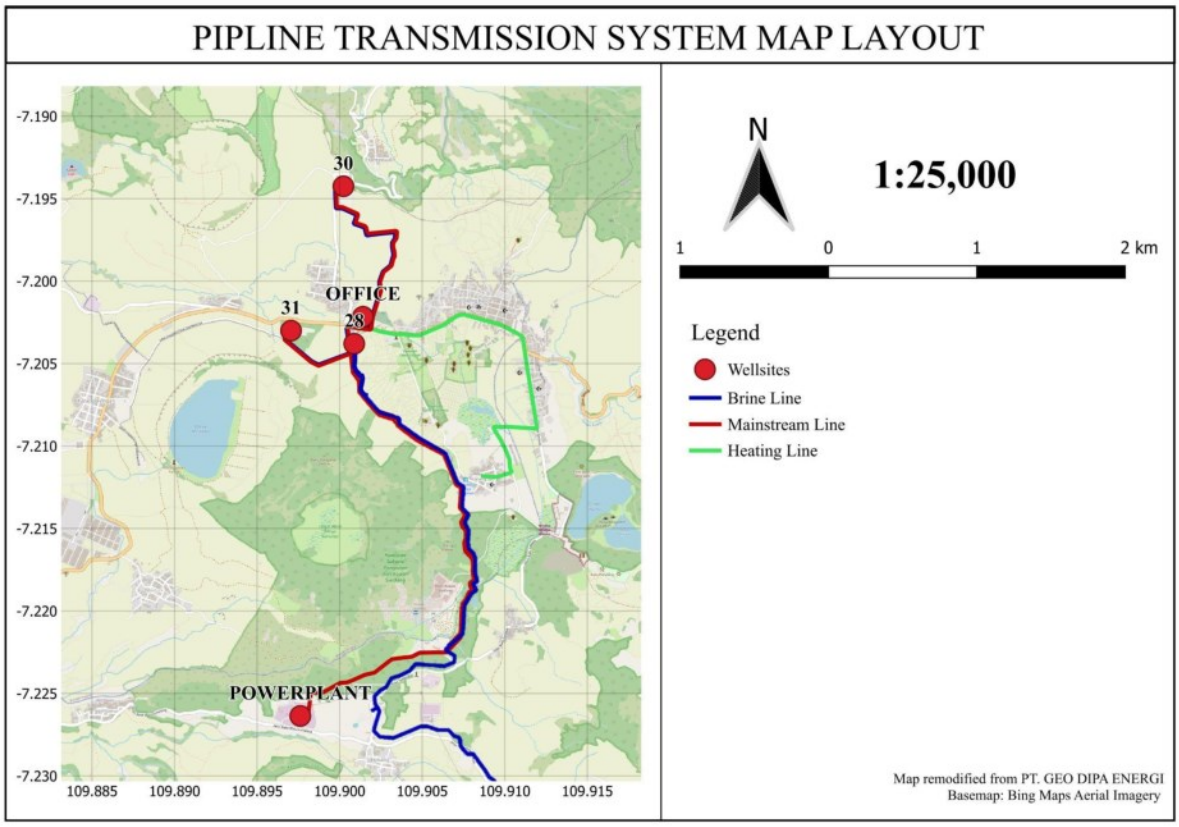

Figure 2: Pipeline Transmission System Map Layout (PT. Geo Dipa Energi in MEMR, 2017).

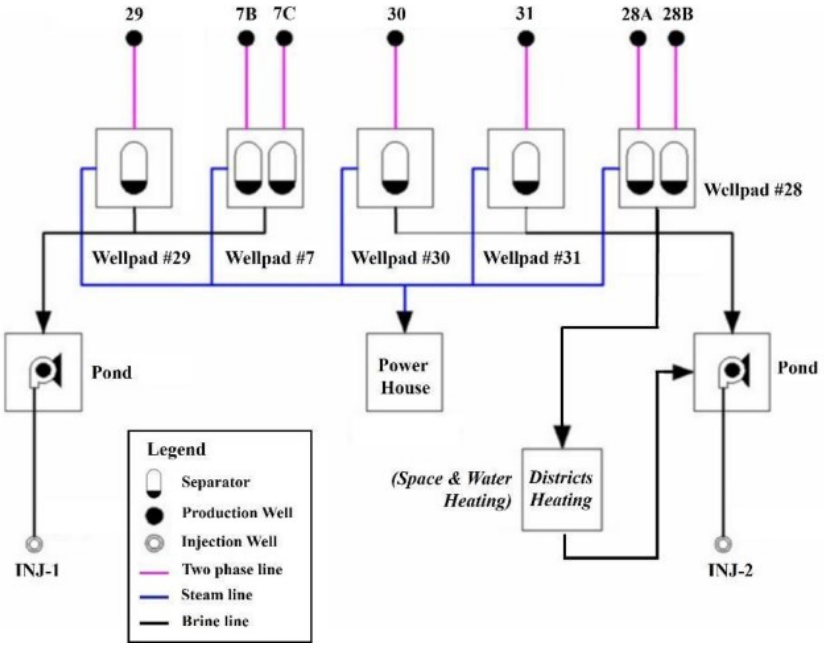

Figure 3: Scheme of brine extraction through pipeline transmission from well pad #28 for district heating (Modified from Pambudi et al., 2015).

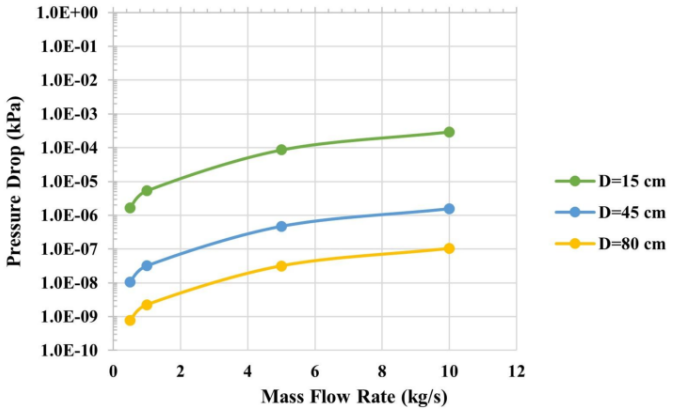

Figure 4: Relationship of changes in mass flow rate and pipe diameter to the pressure drop generated on a logarithmic scale for the selection of district heating transmission pipe dimensions.

Table 4: Interpolation of pressure data with enthalpy from pipeline transmission system due to pressure drop.

Pressure Table (Cengel et al., 2011)	Value (kPa)	Enthalpy (kJ/kg)
P1	1000	762.51
P(2.86 km)	1050 - 8×10^{-10}	**771.77**
P2	1100	781.03

Table 5: Interpolation of temperature data with enthalpy from pipeline transmission system due to pressure drop.

Temperature Table (Cengel et al., 2011)	Value (°C)	Enthalpy (kJ/kg)
T1	180	763.05
T(2.86 km)	**181.97**	771.77
T2	185	785.19

To determine the necessary refrigerant temperature change in the heat exchanger, we can follow the 'rule of thumb' (Lund, 2010). The rule of thumb for determining the temperature in a water heating system heat exchanger is 10/5/5. This rule indicates that 10 is the temperature difference between the water supplied to the water tank and the water temperature, 5 is the temperature difference between the refrigerant entering the heat exchanger and the water supplied to the water tank, and the last 5 is the temperature difference between the refrigerant leaving the heat exchanger and the water temperature. For determining the temperature in a heat exchanger for space heating, the 15/10/10 rule is used. The rule for space heating indicates that 15 is the temperature difference between the air supplied to the space and the air temperature, 10 is the temperature difference between the refrigerant entering the heat exchanger and the air supplied to the space, and the last 10 is the temperature difference between the refrigerant leaving the heat exchanger and the air temperature.

In practice, to achieve a water temperature of 45°C and a room temperature of 20°C, which are the average temperatures at which most people feel comfortable, the temperature design shown in Figure 6 is required.

After the temperatures at the heat exchanger are established, the temperature changes occurring at the compressor and expansion valve can be determined using the T-s diagram shown in Figure 7. Once the temperatures of each component are known, the temperature change of the brine in this condition is calculated by determining the amount of heat required to change the phase of the refrigerant to gas, or Q_L(kJ/kg).

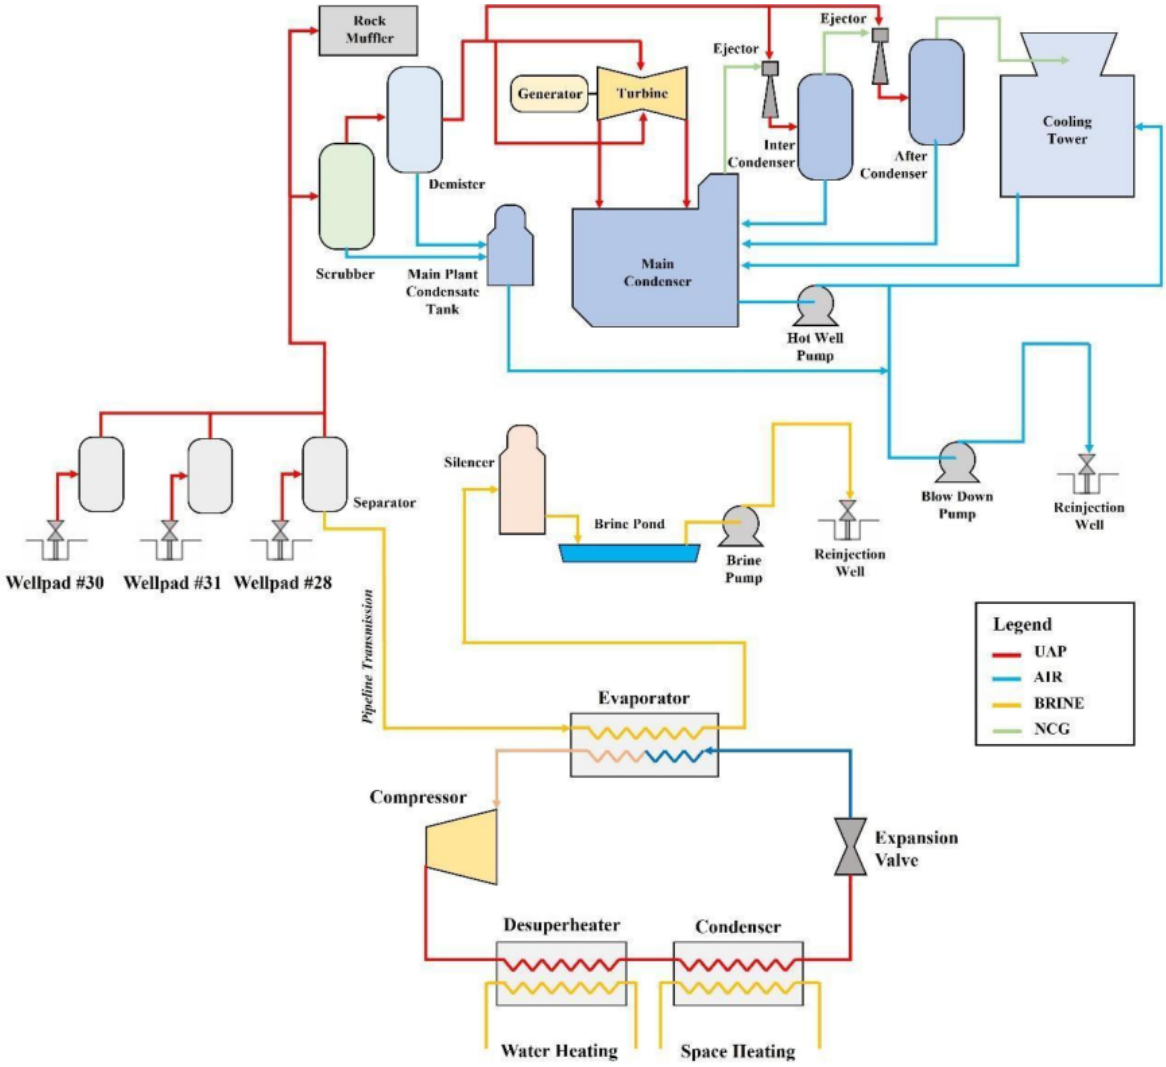

Figure 5: Scheme of district heating system from geothermal power plant.

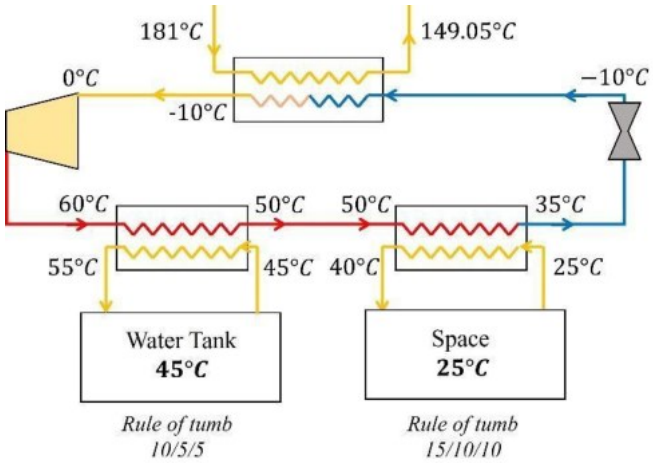

Figure 6: Temperature design of water heating and space heating heat exchanger.

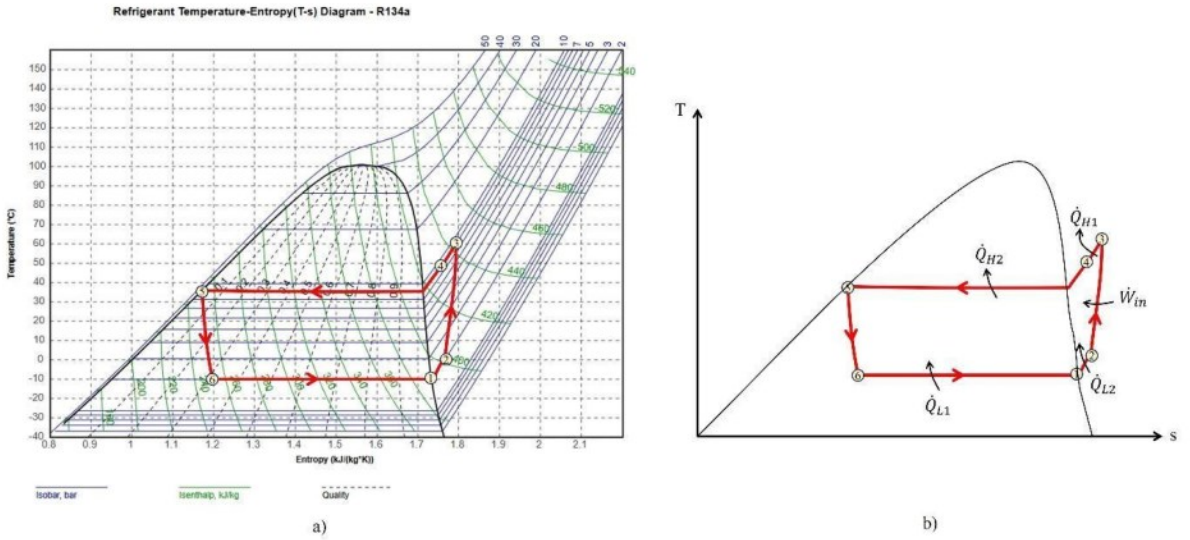

Figure 7: a) T-s diagram for heat pump system cycle,
b) Cycle energy conservation in heat pump system for water and space heating.

Energy conservation equation for the heat pump system is as follows:

$$Q_{H1} + Q_{H2} = Q_{L1} + Q_{L2} + W_{in} \text{ (kJ/kg)} \quad (5)$$

where Q_{H1}, Q_{H2}, $QL1$, Q_{L2} dan W_{in} are the heat transferred to the water heating system, the heat transferred to the space heating system, the heat absorbed from the brine, the heat absorbed from the sub-heating process, and the work input to the compressor.

To calculate the heat and work produced or required, equations (6), (7), and (8) can be used. Once the energy values for each process are determined, Coefficient of Performance (COP) can be calculated according to equation (9) for the actual cycle and equation (10) for the Carnot cycle.

$$Q_L(1 \rightarrow 2) = (h_2 - h_1) \quad (6)$$

$$W_{in}(2 \rightarrow 3) = (h_3 - h_2) \quad (7)$$

$$Q_H(3 \rightarrow 4) = (h_3 - h_4) \quad (8)$$

$$COP_{HP} = Q_H / W_{in} \quad (9)$$

$$COP_{HP,\,Carnot} = 1 / (1 - (T_L/T_H)) \quad (10)$$

After calculating according to Table 6 and 7, it is found that the heat pump COP has a value of 4.62, which means that this heat pump can transfer 4.62 units of heat to the space heating and water heating system for each unit of electrical energy consumed. Meanwhile, the COP of the Carnot heat pump has a value of 5.57. This value is higher because the Carnot cycle is based on ideal conditions, which is a reversible thermodynamic cycle. Thus, the COP Carnot indicates the maximum efficiency limit of this heat pump system is 5.57.

Table 6: parameter values of each heat pump cycle condition.

State	Temperature		Pressure (kPa)	Enthalpy (kJ/kg)	Phase
	°C	K			
1	-10	263	200	392.9	gas
2	0	273	200	401.4	superheated
3	60	333	900	443.5	superheated
4	50	323	900	433.2	superheated
5	35	308	900	249.2	fluid
6	-10	263	200	249.2	x =0.317
Brine in	181	454	1050	771.77	fluid
Brine out	149.05	422.05	1050	628.07	fluid

Table 7: Value of heat transferred and absorbed by each heat pump process.

Process	Heat Transfer	Value (kJ/kg)
6 - 1 (evaporation)	QL1	143.7
1 - 2 (sub-heating)	QL2	8.5
2 - 3 (isentropic)	Win	42.1
3 - 4 (water heating)	QH1	10.3
4 - 5 (space heating)	QH2	184

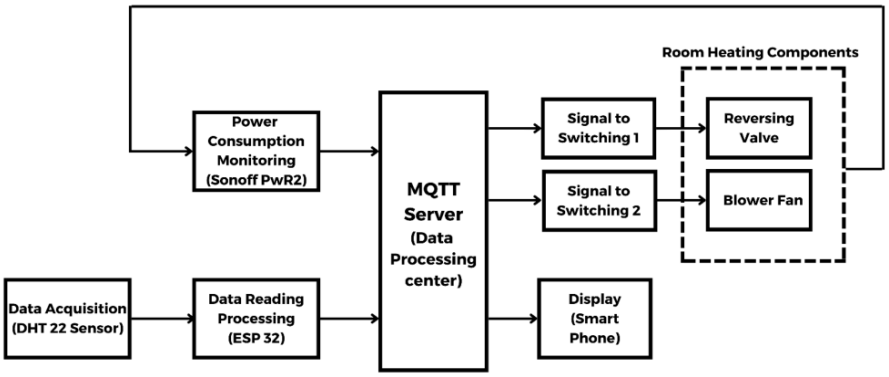

Figure 8: IoT Architecture of the SMART Heating System for Room Heating.

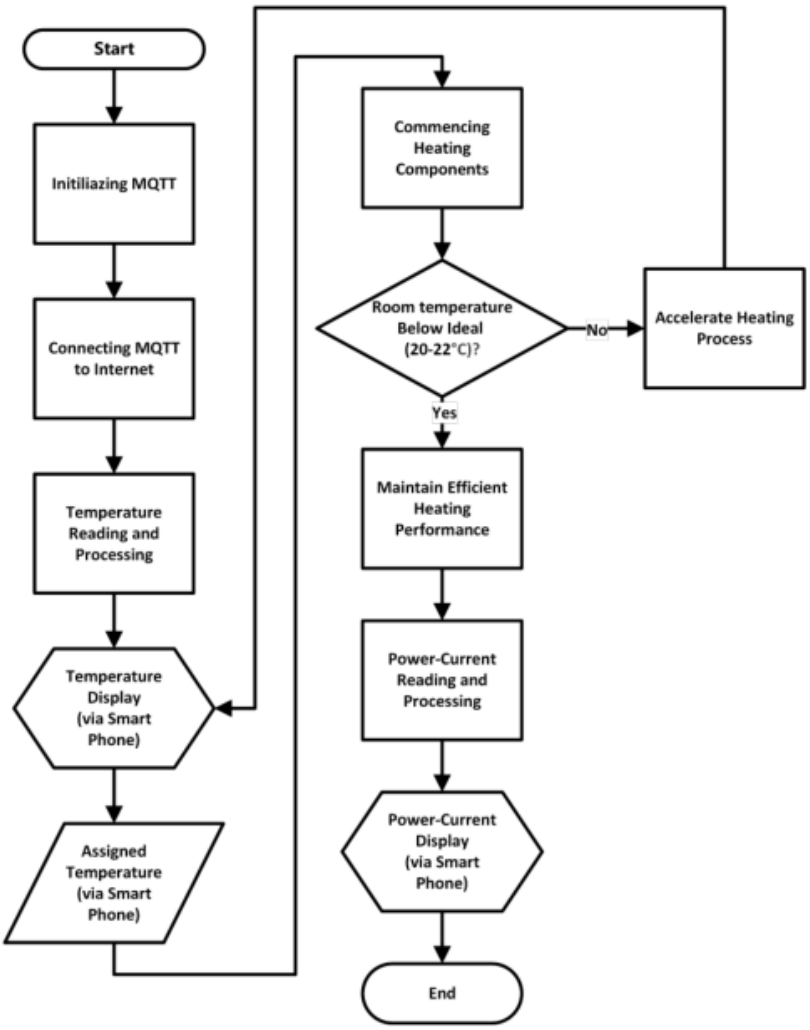

Figure 9: Flow Diagram of the SMART Heating System for Room Heating.

3.2 Automation Scheme in The SMART Heating System

3.2.1 The SMART Heating System for Room Heating

The IoT architecture of the SMART heating System, specifically for room heating, centers around an MQTT (Message Queuing Telemetry Transport) which runs on TCP/IP protocol transport. The MQTT is a broker (server) to which clients are registered. Clients compromise publishers (message or information transferring elements) and subscribers (message or information receiving elements) are registered. The schematic architecture of the SMART Heating System for room heating is as depicted by Figure 8.

Figure 8 shows that temperature data is acquired by DHT 22 sensor and transported to ESP 32 for reading and processing. Then, ESP 32 will publish the information (data processing output) to the server. MQTT will give instructions to other components in accordance with the processing result; the result will be subscribed to the smartphone. To be more specific, the flow diagram, demonstrating how the SMART Heating System operates, is as shown in Figure 9.

Figure 9 shows that the system begins with MQTT initialization. Afterward, the initial room temperature data is acquired and displayed on the smartphone. The user (human input) can assign the desired temperature via mobile phone and the heating components will perform accordingly. If the room temperature is below the desired temperature, then the heating process will be accelerated. When the desired temperature is achieved, the system will maintain its stability; thus, minimizing the inefficient use of energy.

3.2.2 The SMART Heating System for Water Heating

The IoT architecture of the SMART Heating System for water heating utilizes MQTT as the center of data processing. The schematic architecture of the SMART Heating System for water heating is as depicted by Figure 10.

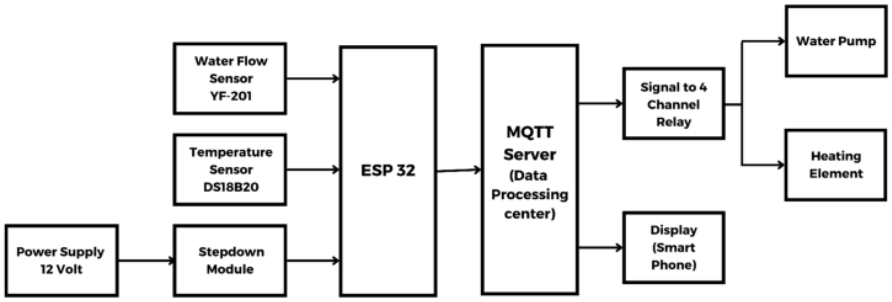

Figure 10: IoT Architecture of the SMART Heating System for Water Heating.

As Shown in Figure 10, the water flow sensor (YF-201) and the temperature sensor (DS18820) acquire the data for ESP 32 to process. Then, the result will be published on the MQTT server. Afterward, the broker will instruct the water pump and heating element (via 4 4-channel relay) to function accordingly. To be more precise, the workflow diagram of the SMART Heating System for water heating is as depicted in Figure 11.

As shown by Figure 11, the system starts with MQTT initialization. Subsequently, the desired temperature and volume will be assigned via smartphone. Pump and heating components will operate accordingly to produce hot water as instructed. Through this mechanism, the system will be able to produce hot water through the efficient use of energy.

3.3 Social Aspect of The SMART Heating System

The implementation of the SMART Heating System, which incorporates the Internet of Things (IoT) concept in the Dieng region, presents significant prospects for improved efficacy and management in the utilization of geothermal energy. Nevertheless, the effectiveness of this technology is heavily reliant on the reception from the local community. This is due to the fact that a technology may satisfy technical criteria, but it may not always be embraced socially. Acceptance of technology is not simply divided into two, but is a continuum that can change over time, either in a positive or negative form (Wolfe et al., 2002).

Based on previous research on the acceptance of geothermal energy advancement in Dieng, it is evident that the community has a high level of knowledge about the benefits of geothermal energy. Specifically, 83% of the community agrees that geothermal energy can be used for electricity production, and 53% believe that this energy will be utilized in the future (Wibowo et al., 2021). The integration of the SMART Heating System with IoT has the potential to be well received by the community. Additionally, the 32% belief that geothermal technology can help prevent global warming indicates a level of environmental awareness that can be further strengthened through additional education on the efficiency and sustainability of this system.

Moreover, the SMART Heating System not only provides an effective and eco-friendly heating solution, but also delivers a variety of important social advantages to the local community and tourism industry in Dieng.

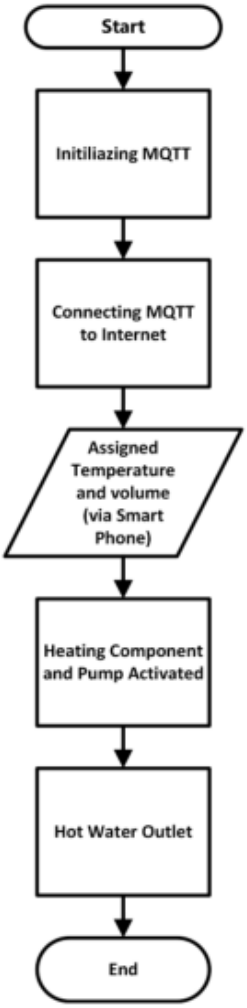

Figure 11: Flow Diagram of the SMART Heating System for Water Heating.

3.3.1 Improved Quality of Life for Local Communities

The integration of IoT technology into the SMART heating system not only grants local residents access to cutting-edge technology but also plays a crucial role in enhancing their comprehension and proficiency in utilizing advanced technology. Through the incorporation of IoT technology, residents will become more adept at utilizing smart devices and automation, consequently enhancing their technical skills. Furthermore, receiving training and education, particularly in the field of renewable energy technology and management, will equip them with practical knowledge on how to operate and maintain the system. Witnessing firsthand the integration of IoT technology with renewable energy sources like geothermal energy will help individuals realize that environmentally friendly energy is not merely a theoretical concept but something that can be put into practice and utilized daily. Therefore, the utilization of IoT technology in renewable energy-based water and space heating systems can serve as a significant catalyst for fostering more environmentally conscious behavior among local communities.

3.3.2 Environmental Impact Reduction

This technology aims to enhance energy efficiency through the utilization of geothermal waste, which has not been fully utilized until now. By decreasing reliance on fossil fuels, the system will contribute to the reduction of greenhouse gas emissions, thereby supporting initiatives to mitigate climate change. Furthermore, the integration of IoT allows for more efficient monitoring and management, which in turn promotes improved and sustainable waste management practices.

3.3.3 Safety of Use

IoT systems facilitate the automated monitoring and regulation of heating systems, which can enhance safety and minimize the chances of fire or malfunction. Through sensors and interconnected devices, issues can be identified and addressed promptly. Additionally, remote control functionality allows for swift responses to emergencies, thereby improving user and property safety.

3.3.3 Tourism Attraction Enhancement

The implementation of the SMART Heating System will have a significant positive impact on travelers in Dieng. Through the utilization of this innovative technology, tourists will enjoy enhanced lodging standards, resulting in heightened comfort levels due to the provision of steady and dependable heating. This enhancement not only boosts tourist contentment but also bolsters Dieng's reputation as a contemporary and environmentally conscious tourist spot. Furthermore, the system serves as an extra draw for environmentally and sustainability-conscious travelers, thereby promoting sustainable tourism.
